Humla v0.3

# Good Performance

- What influences good performance?
  - *Number of users and concurrent connections*
  - *Number of messages and messages' sizes*
  - *Number of services*
  - *Infrastructure – capacity, availability, configuration, ...*
- How can we achieve good performance?
  - *Infrastructure*
    - *Scalability, failover, cluster architectures*
  - *Performance tuning*
    - *Application Server, JVM memory, OS-level tuning, Work managers configuration*
  - *Service configuration*
    - *Parallel processing, process optimization*

# Overview

- Infrastructure
  - *Load Balancers*
  - *Cluster Architecture*
- Performance Tuning

# Definitions

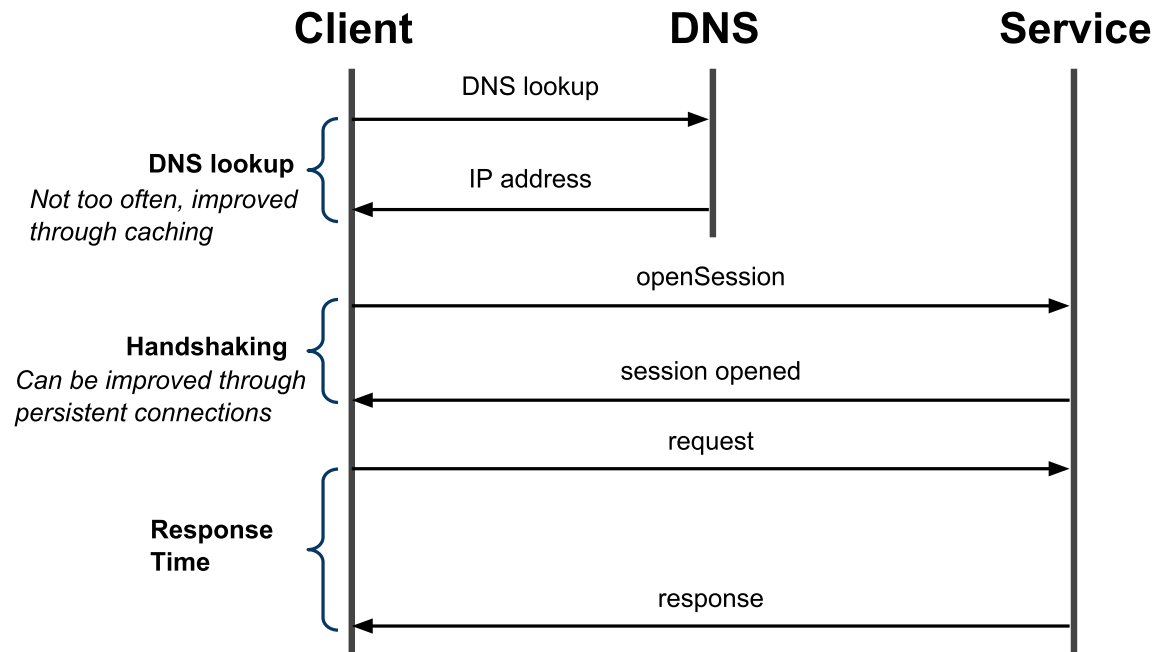

- Scalability
  - *server scalability*
    - *ability of a system to scale – when input load changes*
    - *users should not feel a difference when more users access the same application at the same time*
    - **horizontal scaling**
      - *adding new instances of applications/servers*
    - **vertical scaling**
      - *adding new resources (CPU, memory) to a server instance*
  - *network traffic*
    - *bandwidth capacity influences performance too*
    - *service should limit the network traffic through caching*
- Availability
  - *probability that a service is operational at a particular time*
    - *e.g., 99.9987% availability – downtime ~44 seconds/year*

## Definitions (Cont.)

- High Availability
  - *When a server instance fails, operation of the application can continue*
  - *Failures should affect application availability and performance as little as possible*
- Application Failover
  - *When an application component performing a job becomes unavailable, a copy of the failed object finishes the job.*
  - *Issues*
    - *A copy of the failed object must be available*
    - *A location and operational status of available objects must be available*
    - *A processing state must be replicated*
- Load Balancing
  - *Distribution of incoming requests across server instances*

# Performance Metrics

- Response Time
  - *A client-side metric*

- *CPU intensive service or a bad configuration of a service*
  - *consider asynchronous processing when CPU intensive*
- *Writing to a data store*

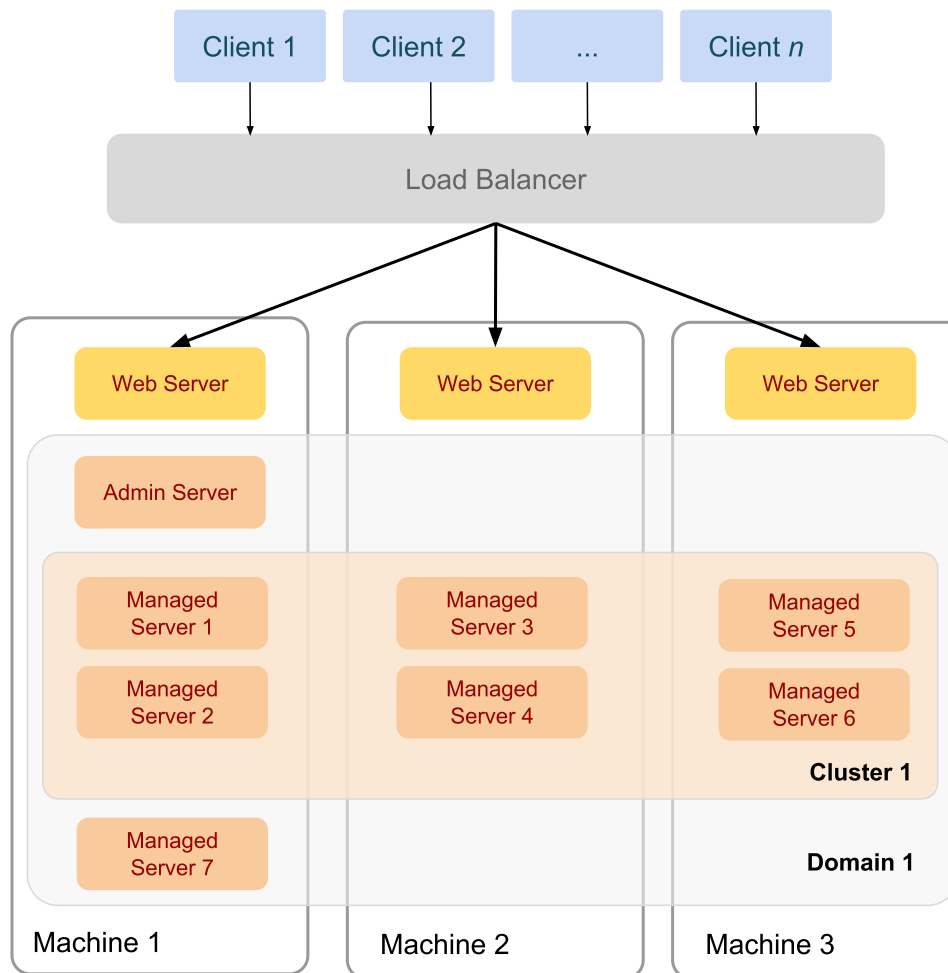

# Performance Metrics

- Queries/Requests per Second (QPS)
  - *A server-side metric*

- *Caching may improve performance*
  - *even if data changes often, with high QPS caching improves a lot*

# Infrastructure Example – Weblogic

## Clients

Clients access objects or applications running on application server.

## Load Balancer

External to application server. Distributes incoming requests to servers running on multiple machines.

## Web Tier

Provides access to servers running in a domain on machines.

## Domain

Collection of clusters and servers. Each domain contains one Admin Server.

## Cluster

Collection of managed servers. Each managed server contains the same copy of objects.

# Best Configuration Practices

- Domain configuration
  - *A server is an admin server or a managed server*
  - *Each server is running on a separated JVM*
  - *A physical machine may run one or more servers*
  - *There should be at least two managed servers running on one machine*
    - *This provides a better performance*  
*(as opposed to one server running on one machine)*
  - *A domain can have clustered or unclustered servers*
- Load balancers (LB)
  - *Load Balancers are not part of the domain*
    - *They are external to Weblogic server*
    - *There is usually one HW LB and several SW LBs*
    - *Software LB*
      - *Realized by the Web Tier (Apache HTTP server)*
      - *Redirects requests too all managed servers in a domain (across multiple machines)*

# Overview

- Infrastructure
  - *Load Balancers*
  - *Cluster Architecture*
- Performance Tuning

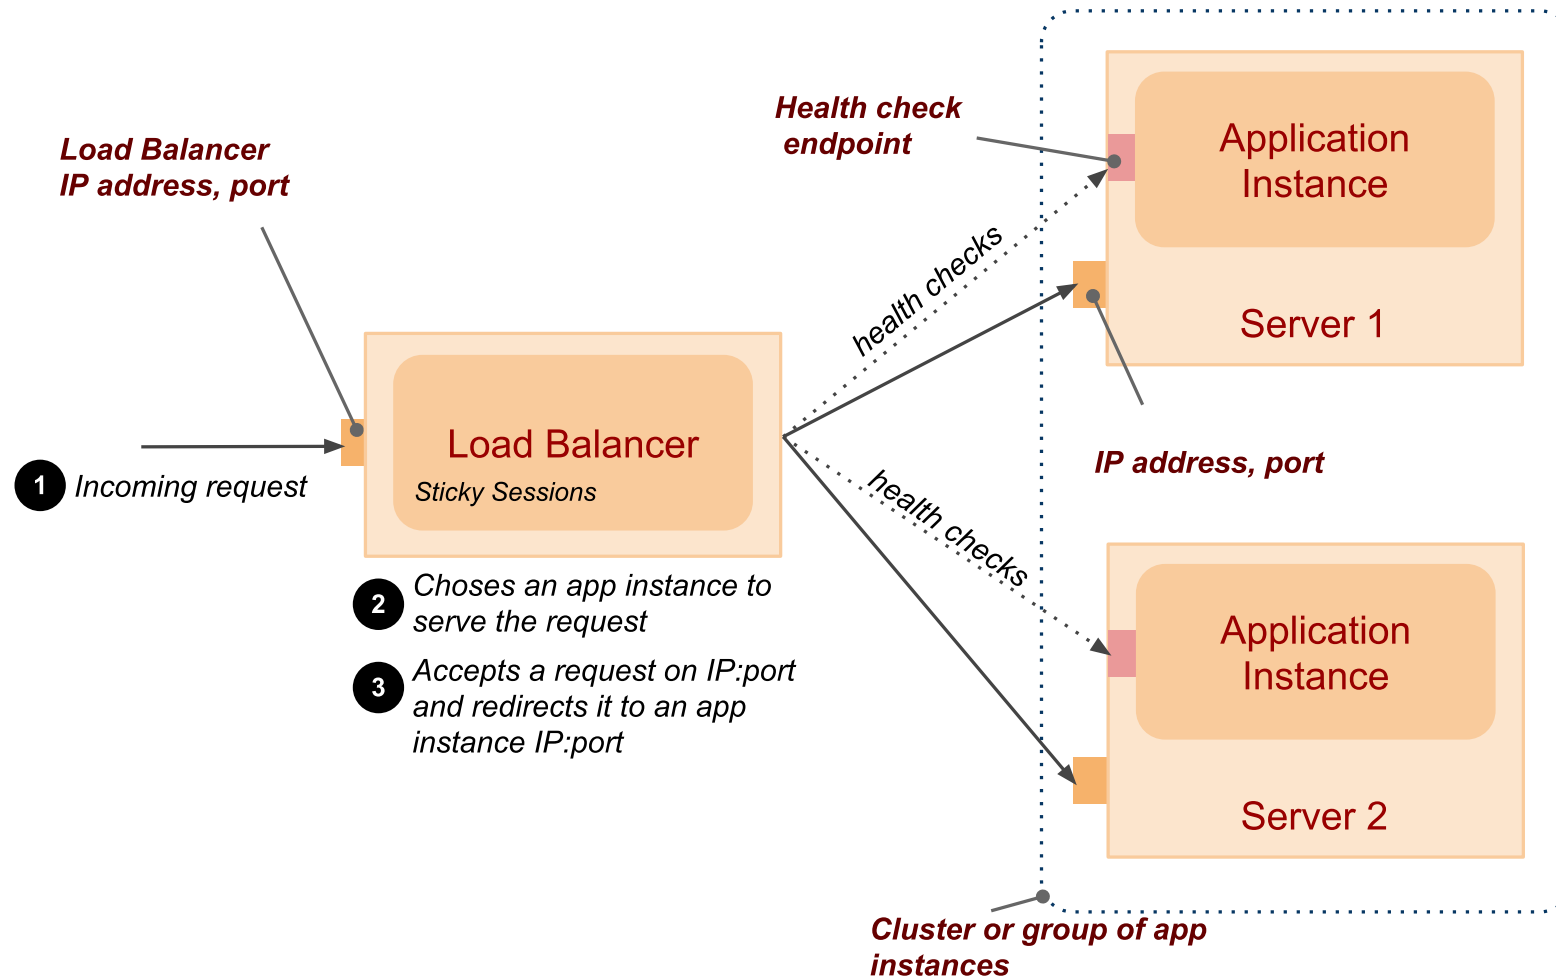

# Load Balancing

- Distributes a load to multiple app/object instances
  - *App instances run on different machines*
  - *Load sharing: equal or with preferences*
  - *Health checks*
- Types
  - *DNS-based load balancer*
    - *DNS Round Robin*
  - *NAT-based load balancer (Layer-4)*
  - ***Reverse-proxy load balancer (Layer-7)***
    - *application layer*
    - *Sticky sessions*
      - *JSession, JSession-aware load balancer*
  - *Client-side load balancer*
    - *LB run by a client*
    - *a client uses a replica-aware stub of the object from the server*

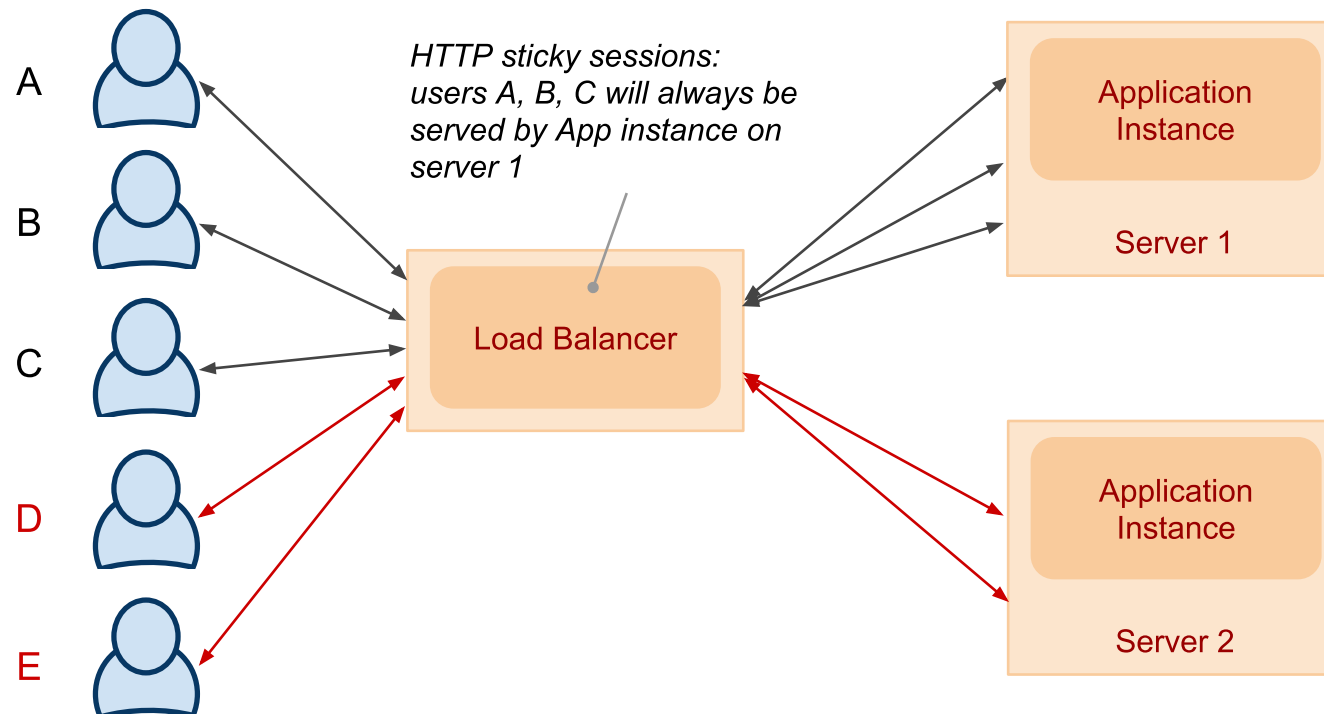

# DNS-based Load Balancer

- DNS Round Robin
  - *A DNS record has multiple assigned IP addresses*
  - *DNS system delivers different IP addresses from the list*
  - *Example DNS A Record:*  
`company.com A 147.32.100.71 147.32.100.72 147.32.100.73`
- Advantages
  - *Very simple, easy to implement*
- Disadvantages
  - *IP address in cache, could take hours to re-assign*
  - *No information about servers' loads and health*

# Reverse Proxy Load Balancer

# HTTP Sticky Sessions Example

- How to identify a server that hosts the session state
  - *Passive cookie persistence* – LB uses a cookie from the server
  - *Active cookie persistence* – LB adds its own cookie

# Types of Load Balancers

- Software

- *Apache mod\_proxy\_balancer*

- *HTTP Session persistence – sticky sessions*

- *WebLogic proxy plug-in*

```
1 <Location /soa-infra>
2     SetHandler weblogic-handler
3     WebLogicCluster czfmwapp03-vf:8001,czfmwapp04-vf:8001,czfmwapp05-vf:8001
4 </Location>
5
```

*/soa-infra* is a first part of an URL path that rules in this **Location** will be applied (this is a standard Apache configuration mechanism)  
**czfmwapp{N}** is a hostname that corresponds to a virtual IP to which the managed server JVM processes is bounded (using the tcp port **8001**).

**WebLogicCluster** specifies the list of servers for load balancing

- Hardware

- *Cisco, Avaya, Barracude*

# Round-Robin Algorithm

- Uses
  - request** – *client request with or without a cookie information*
  - server\_list** – *a list of servers that can process the request*
  - rbinx** – *round robin index*
  - sticky\_sessions** – *associative array of pairs <session\_id,server>*
  - unhealthy\_treshhold** – *a number of negative consecutive health checks before moving the server to the "unhealthy" state.*
- Round Robin Algorithm
  - if **session\_id** exist in the **request** and in **sticky\_sessions**
    - send the **request** to the server **sticky\_sessions[session\_id]**
  - otherwise
    - send the **request** to the **rbinx** server in the **server\_list**
    - extract **session\_id** from the response from the server
    - if the **session\_id** exist, add a pair <**session\_id**;server\_list[rbinx]> to **sticky\_sessions**
    - increase **rbinx** by one or reset it to 0 if it exceeds the length of **server\_list**

# Health Check

- Health Check
  - For each server in the `server_list`
    - call the server's healthcheck endpoint
    - if a number of failed health checks for the server exceeds the `unhealthy_threshold`
      - remove the server from the `server_list`
    - if the server was unhealthy and there was a successful healthcheck
      - add the server back to the `server_list`

# Session State Persistence and Replication

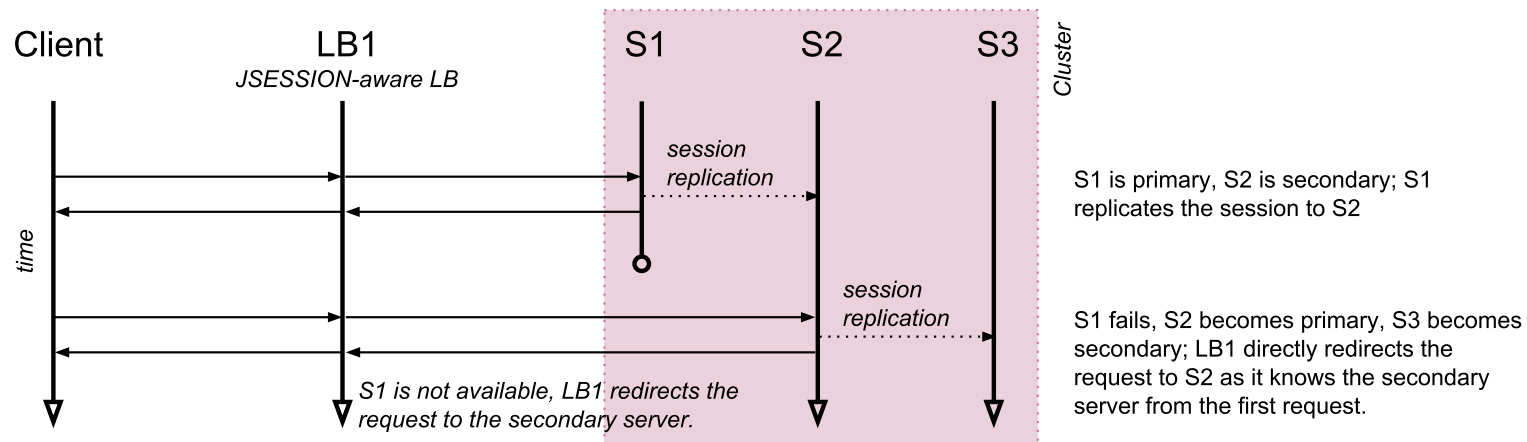

- Session persistence
  - Session information is maintained in the database
  - Does not require sticky sessions
  - Implements `HttpSession` interface that writes data to the DB
- In-memory replication
  - A **primary server** holds a session state, the **secondary server** holds its replica.
  - Information about primary and secondary servers are part of `JSession`

# In-Memory Replication

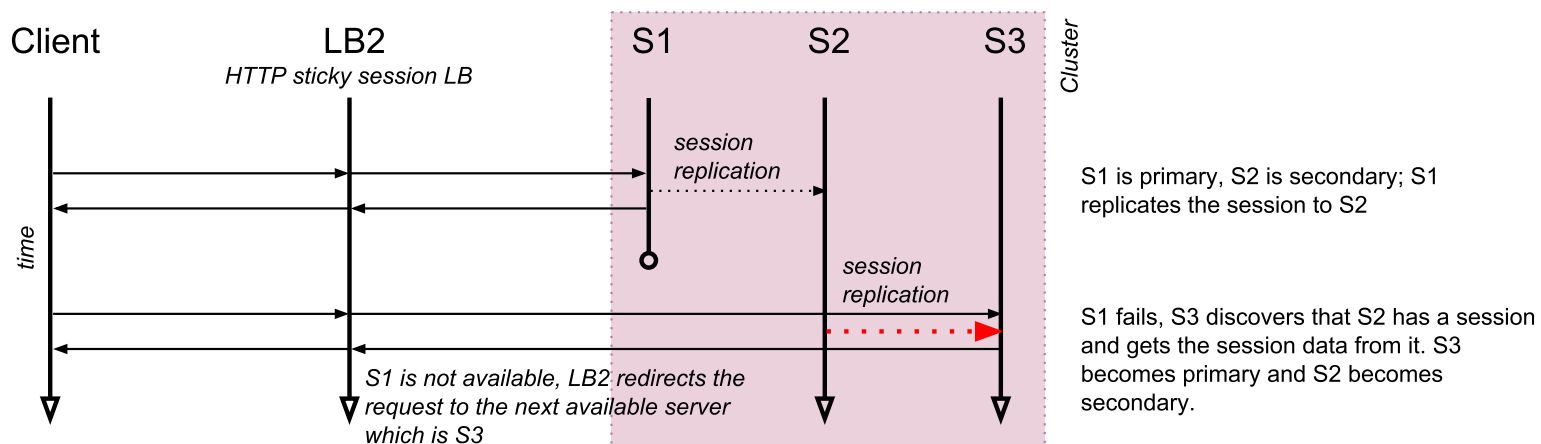

- Session format
  - *It's a cookie*
  - `JSESSIONID=SESSION_ID!PRIM_SERVER_ID!SEC_SERVER_ID!CREATION_TIME`
    - `SESSION_ID` – *session id, generated by the server to identify memory associated with the session on the server*
    - `PRIM_SERVER_ID` – *ID of the managed server holding the session data*
    - `SEC_SERVER_ID` – *ID of the managed server holding the session replica*
    - `CREATION_TIME` – *time the session data was created/updated*
- How LB uses this information
  - *LB has information whether the server is running or not (via healthchecks)*
  - *if the primary server is running, it redirects the request there*
  - *if the primary server is not running, it redirects the request to the secondary server directly*
  - *if primary and secondary servers are not running, it redirect the request to any other server it has in the list – this may cause side effects!*

# In-Memory Replication Scenarios

## Scenario A: JSession-aware load balancer

## Scenario B: HTTP sticky session load balancer

# Overview

- Infrastructure
  - *Load Balancers*
  - *Cluster Architecture*
- Performance Tuning

# Overview

- Cluster capabilities
  - *A group of servers (aka cluster members) act together to serve clients' requests*
  - *Cluster is transparent to clients*
  - *Servers can run on the same machines or on different machines*
  - *Cluster's capacity can be increased by adding servers to the cluster*
  - *Servers in a cluster may have the same copy of objects and they are aware of each other objects*
    - *objects: applications, JMS destinations, RMI objects*
    - *See [Cluster-wide JNDI tree](#) in Lecture 4*
- Cluster Messaging Protocols
  - *When servers need to send messages to other members of the cluster*
  - **Unicast** - *one-to-one communication using TCP/IP sockets*
  - **Multicast** - *one-to-many communication*
  - *Cluster services that rely on the cluster messaging protocol*
    - *Cluster Membership*
    - *JNDI Replication*
  - *There are services using persistent RMI connections between cluster members*
    - *such as during in-memory replication of HTTP session information*

# Unicast

- Overview
  - Uses standard TCP/IP sockets to send messages across cluster members
  - Uses a **group leader strategy** to limit the number of sockets required to send messages within the cluster
- Groups in the cluster
  - Cluster is split into **M** groups with **N** servers, each group has a leader
  - Servers communicate with the group leader, group leaders communicate with servers in the group and other group leaders
  - When a group leader dies, the group elects another group leader
  - There is up to **MxN** network messages for every cluster message

# Cluster Services

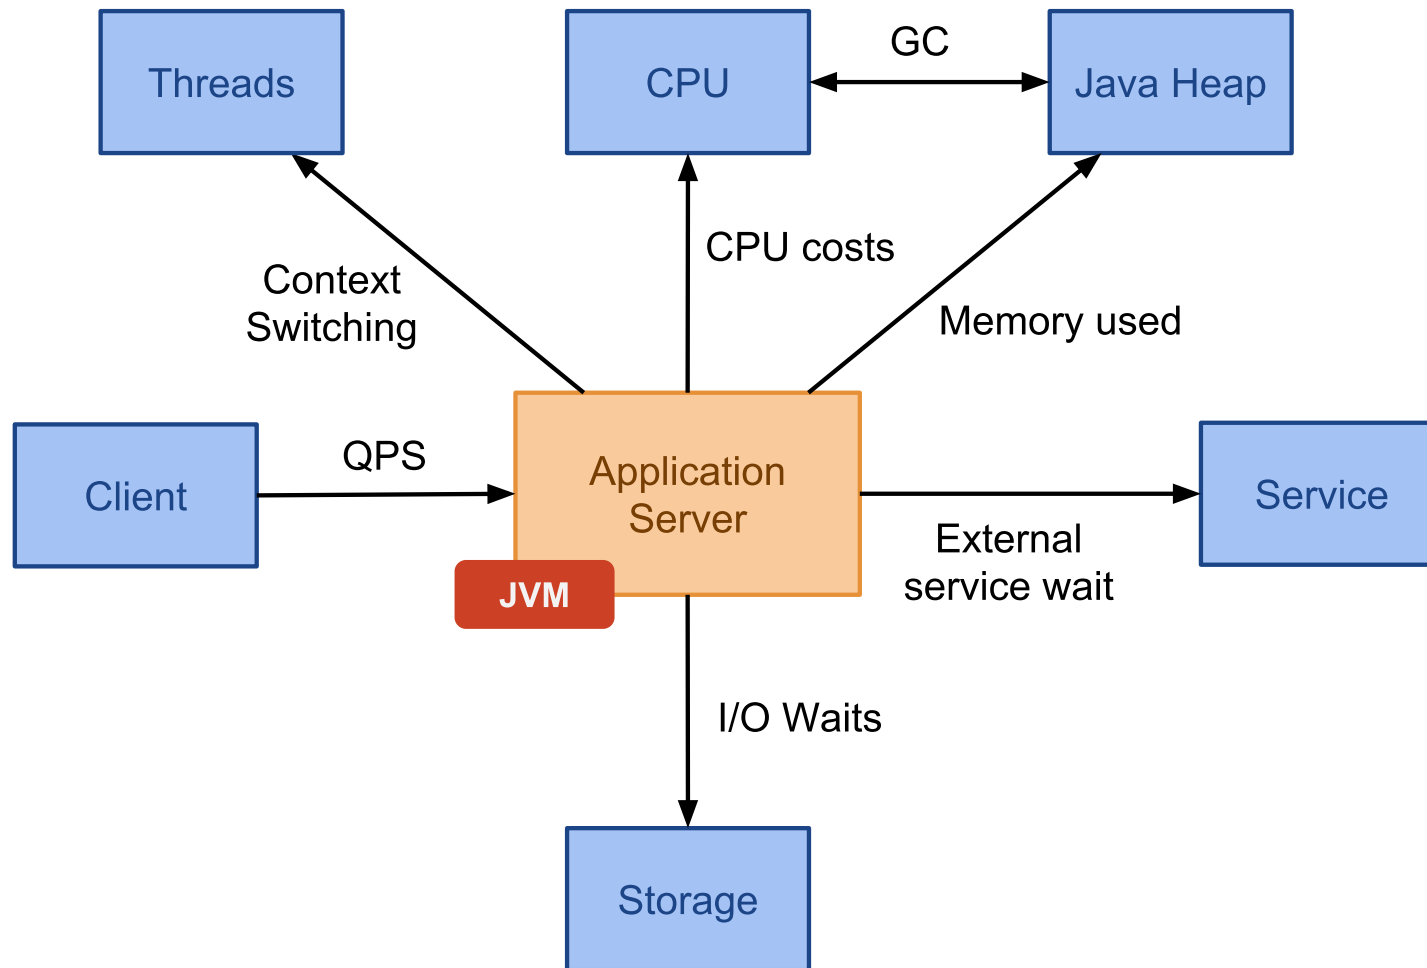

- Cluster Membership
  - *Cluster members maintain their view on what servers are in the cluster*
  - *Each server sends heartbeat messages to the cluster*
    - *others know it is alive*
  - *Each server receives heartbeat messages*
    - *When a server misses a number of messages from a cluster, it removes the server from the list until it receives the next heartbeat message.*
- JNDI Replication
  - *Provides each server with a cluster-wide view of the JNDI tree.*
  - *Servers send JNDI update messages to the cluster when an object is bound or removed to their local tree.*
  - *When a server leaves the cluster*
    - *other members remove its JNDI bindings from their tree.*
  - *When a server joins the cluster*
    - *The server asks other server for a JNDI state dump.*

# Overview

- Infrastructure
- Performance Tuning

# Performance Limiting Factors

# Monitoring

- Important to understand performance
  - *DevOps monitoring trends*
- What you need
  - *Collect → Filter → Store → View → **Tune***
  - *Metrics, dashboards, alerting, log management, reporting, tracing capabilities*
  - *It is necessary to organize metrics well in order to understand what is going on*
  - *Start from a high-level process, detail to technical components*
- Source
  - *Application server*
    - *usually management beans with JMX interfaces*
    - *log files (access logs, server logs, etc.)*
  - *OS*
    - *many utilities available out of the box*
    - *open sockets, memory, context switches, I/O performance, CPU usage*
  - *Database*
    - *applications may write metrics to the DB*
    - *SQL scripts to collect metrics*

# Monitoring Tools

- Commercial Monitoring Solutions
  - *Application server vendor usually offers a monitoring solution*
  - *AppDynamics, Oracle Enterprise Manager, Splunk*
  - *Google stackdriver, Amazon AWS CloudWatch*
- Open source examples
  - *Elasticsearch + LogStash + Kibana*
  - *InfluxDB + Telegraph + DataGraph*

# Tuning – A Layered Approach

- Application server can be tuned at multiple layers
  - *Service configuration optimization*
  - *Transport-level tuning*
  - *Application Server Tuning*
  - *JVM Memory Tuning*
  - *OS Tuning*
- Lower levels are cheaper to tune

# Memory Allocations

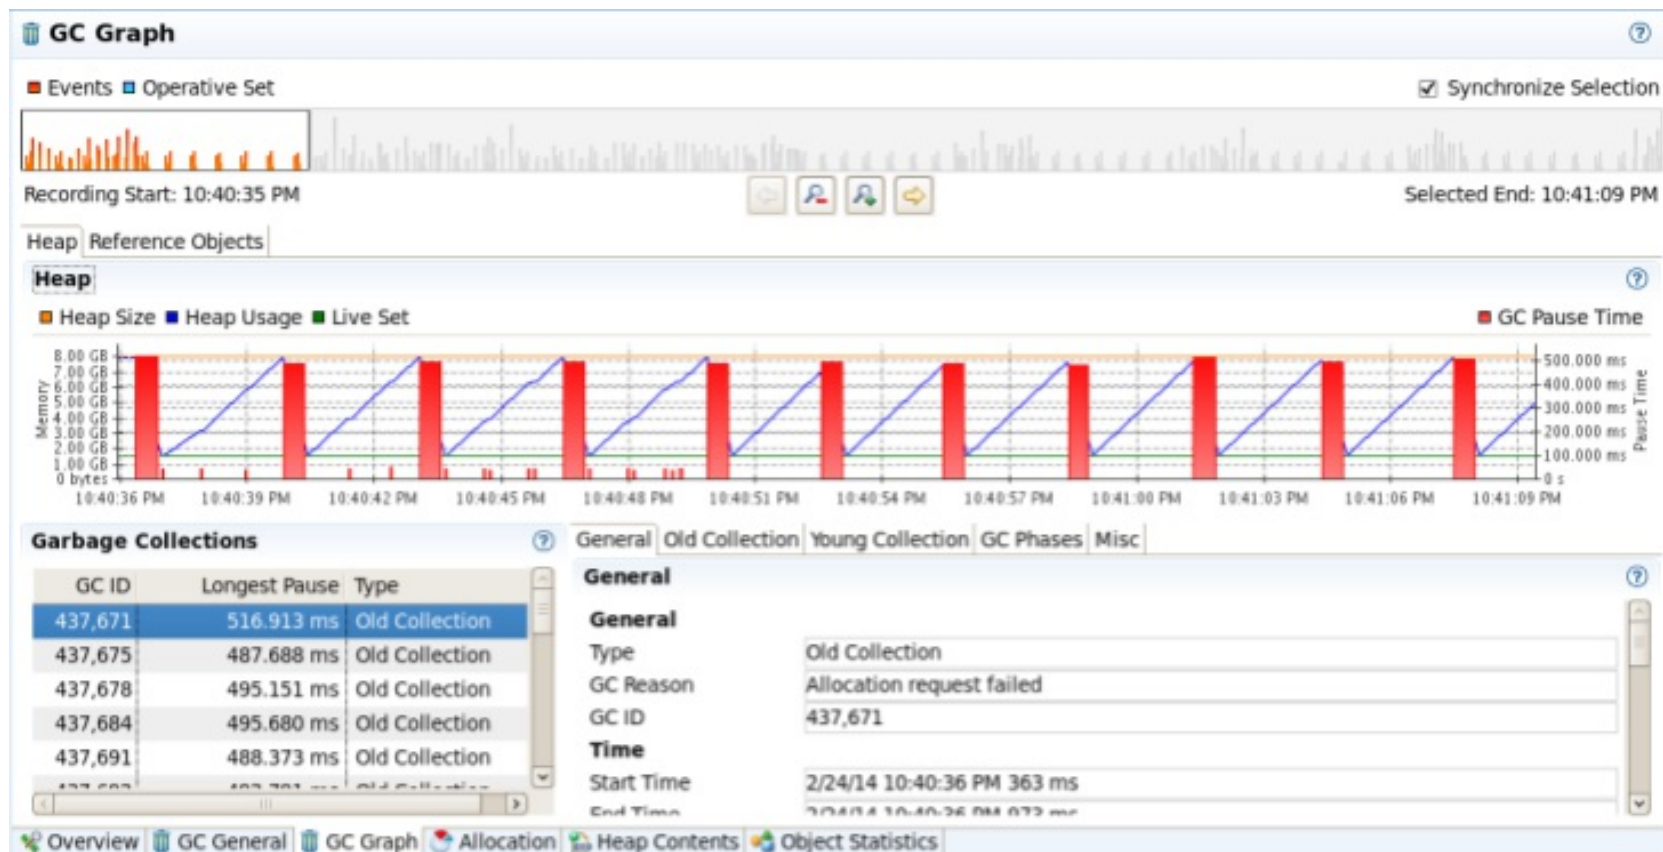

- Generations
  - *Young* – objects get allocated in this space initially
  - *Old* – objects get promoted to old from young
  - *Perm* – space for permanent allocations, e.g. objects describing classes and methods

# Garbage Collection

- Steps to move objects around
  1. *Objects are created in young*
  2. *When young is full, the live objects are copied to old, dead are discarded*
    - **lightweight GC**
  3. *When young is full and no space in old → the full GC frees the old space*
    - **Full GC** – *nothing is running in JVM, the application stops*
    - **Too frequent full GC has an impact on performance**
- A memory leak or inadequate heap allocation
  - *Old is out of space → full GC will run often (or continuously)*
  - *High CPU utilization, The server will not be able to process/respond to requests*

# Heap Size and GC Runs

- Heap Size and GC runs
  - *Wrong heap size allocation – too small or memory leaks*
  - *GC full runs too often, this has a negative impact on performance*

# JVM Memory Tuning

- JVM Memory Parameters

- Xms – *initial java heap size*

- Xmx – *maximum java heap size*

- XX:NewSize – *the initial size of the heap for young generation*

- XX:MaxNewSize – *the maximum size of the heap for young generation*

- General recommendations

- Xms and -Xmx should be set to the same value

- (do not allow the heap to grow → limit the overhead)

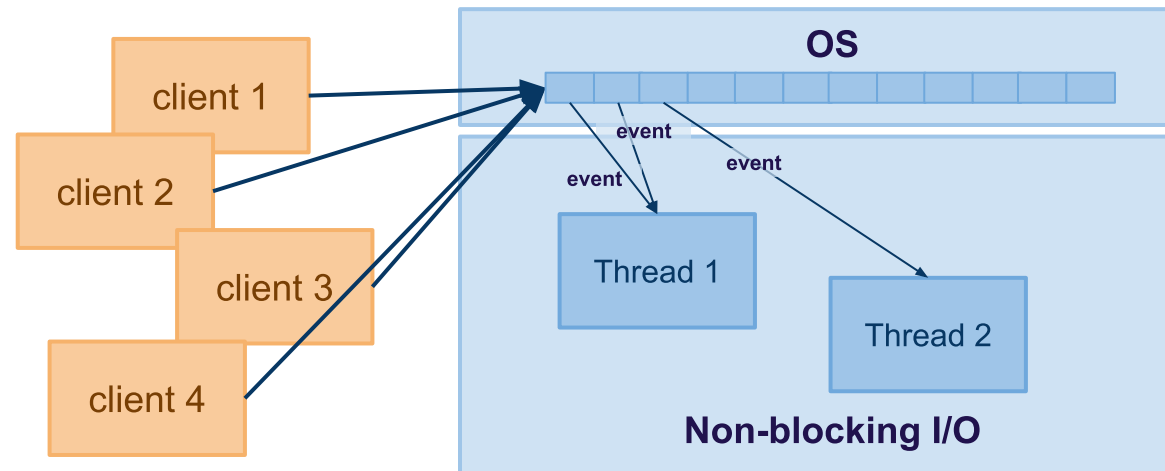

- XX:NewSize and -XX:MaxNewSize should be set to the one half of maximum heap

- Example, 1GB heap size

- Xms1024m -Xmx1024m -XX:NewSize=500m -XX:MaxNewSize=500m

# Asynchronous I/O: Recall

- Connections maintained by the OS, not the Web app
  - *The Web app registers events, OS triggers events when occur*

- Characteristics
  - *Event examples: new connection, read, write, closed*
  - *The app may create working threads, but controls the number!*
    - *much less number of working threads as opposed to blocking I/O*

# Work Manager Configuration

- Work Manager
  - Controls the number of thread allocated to processing of requests
  - In WLS is called a dispatch policy
    - Can be assigned to OSB proxy services
  - Parameters
    - **maximum threads** (**max**) – maximum number of working threads
    - **capacity** (**cap**) – maximum number of connections
  - maximum connections waiting to be processed: **cap - max**
  - refused connections: when number of connections is **> cap**
- Inbound throttling
  - A dispatch policy applied to a single proxy service
  - Rejected connections will not be processed
