Modified: Tue Jan 30 2018, 10:26:51
Humla v0.3

Overview

- Introduction to Application Protocols
 - *Synchronous and Asynchronous Communication*
 - *Selected Networking Concepts*
- Introduction to HTTP

Application Protocols

- Remember this

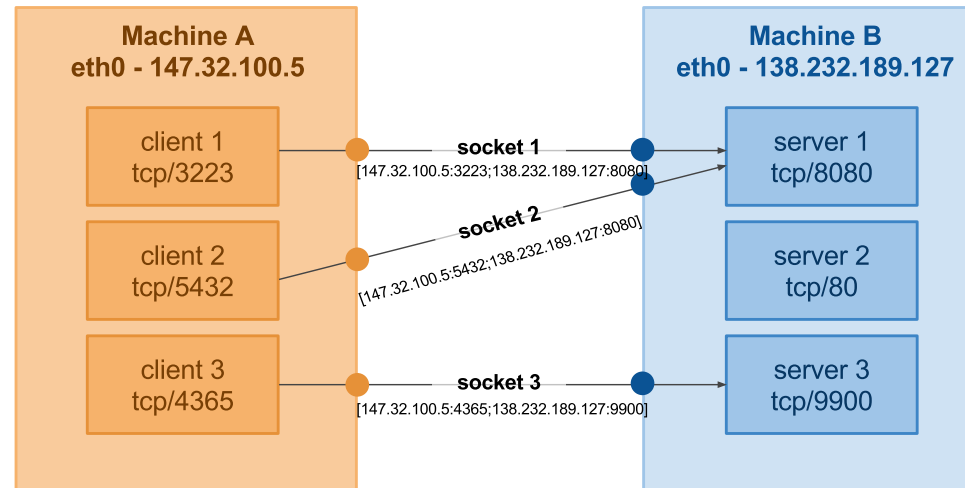

- App protocols mostly on top of the TCP Layer
 - *use TCP socket for communication*
- Major protocols
 - *HTTP – most of the app protocols layered on HTTP*
 - *wide spread, but: implementors often break HTTP semantics*
 - *RMI – Remote Method Invocation*
 - *Java-specific, rather interface*
 - *may use HTTP underneath (among other things)*
 - *XML-RPC – Remote Procedure Call and SOAP*
 - *Again, HTTP underneath*
 - *WebSocket – new protocol part of HTML5*

Socket

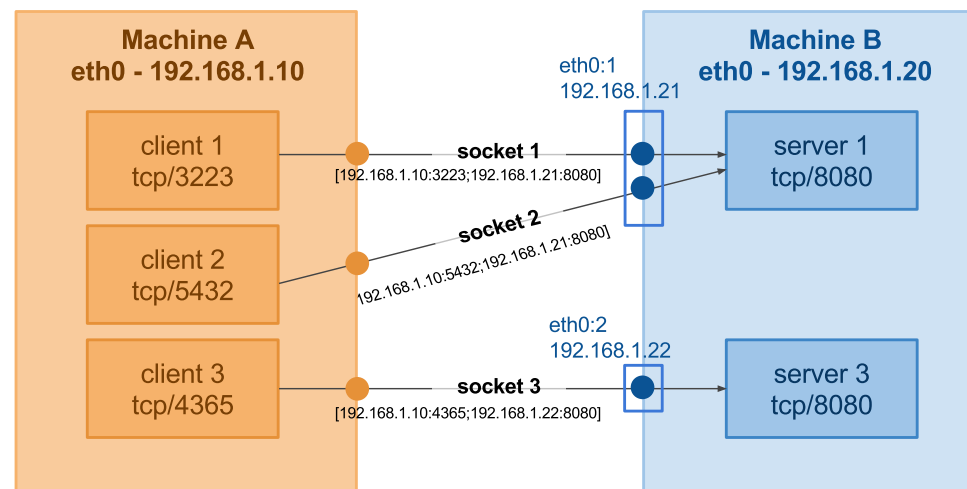

- Handshaking (connection establishment)
 - The server listens at `[dst_ip,dsp_port]`
 - Three-way handshake:
 - the client at `[src_ip,src_port]` sends a connection request
 - the server responds
 - the client acknowledges the response, can send data along
 - Result is a socket (virtual communication channel) with unique identification:
`socket=[src_ip,src_port;dst_ip,dst_port]`
- Data transfer (resource usage)
 - Client/server writes/reads data to/from the socket
 - TCP features: reliable delivery, correct order of packets, flow control
- Connection close

Addressing in Application Protocol

- IP addressing: IP is an address of a machine interface
 - A machine can have multiple interfaces (*eth0, eth1, bond0, ...*)
- TCP addressing: TCP port is an address of an app running on a machine and listening on a machine interface
 - Multiple applications with different TCP ports may listen on a machine interface
- Application addressing
 - Additional mechanisms to address entities within an application
 - They are out of scope of IP/TCP, they are app specific
 - for example, Web apps served by a single Web server

Virtual IP

- Virtual IP
 - Additional IP addresses assigned to a network interface
 - For example, `eth0` – `eth0:1`, `eth0:2`, `eth0:3`, ...
 - A process can bind to the virtual IP
 - Multiple processes can listen on the same tcp port but on different virtual IPs
- Benefits
 - Floating IP – a process can move transparently to another physical machine
 - Network configuration can be preserved, no need to reconfigure
 - Failover concept uses floating IPs

Virtual IP Configuration

- Steps to configure virtual IP in Linux (example for **eth0**)

1. Find out the interface's network mask

```
1 | $ ifconfig eth0
2 | eth0      Link encap:Ethernet  HWaddr 00:0C:29:AB:5E:6A
3 | inet addr:172.16.169.184  Bcast:172.16.169.255  Mask:255.255.255.0
4 | ...
```

2. Create virtual IP using **ifconfig**

– it should use the same network mask

– it should be free, usually allocated to be used as a virtual IP

```
5 | $ sudo ifconfig eth0:1 172.16.169.186 netmask 255.255.255.0
6 | $ ifconfig eth0:1
7 | eth0:1    Link encap:Ethernet  HWaddr 00:0C:29:AB:5E:6A
8 |          inet addr:172.16.169.186  Bcast:172.16.169.255  Mask:255.255.255.0
```

3. Update neighbours' ARP (Address Resolution Protocol) caches

– to associate the virtual IP with MAC address of **eth0**

– when the virtual IP was in use on other node or interface

```
9 | $ sudo arping -q -U -c 3 -I eth0 172.16.169.184
```

Tasks

– Configure a virtual IP on your computer and test it using **ping**

Server Failover

- Failover
 - *Failover = ability to relocate the server to another machine without an impact on the performance*

- *Managed server listens on **virtual_IP:port***
- *A load balancer forwards a request to **virtual_IP:port***
- *When the server moves, **virtual_IP:port** remains the same*

Overview

- Introduction to Application Protocols
 - *Synchronous and Asynchronous Communication*
 - *Selected Networking Concepts*
- Introduction to HTTP

Synchronous and Asynchronous Communication

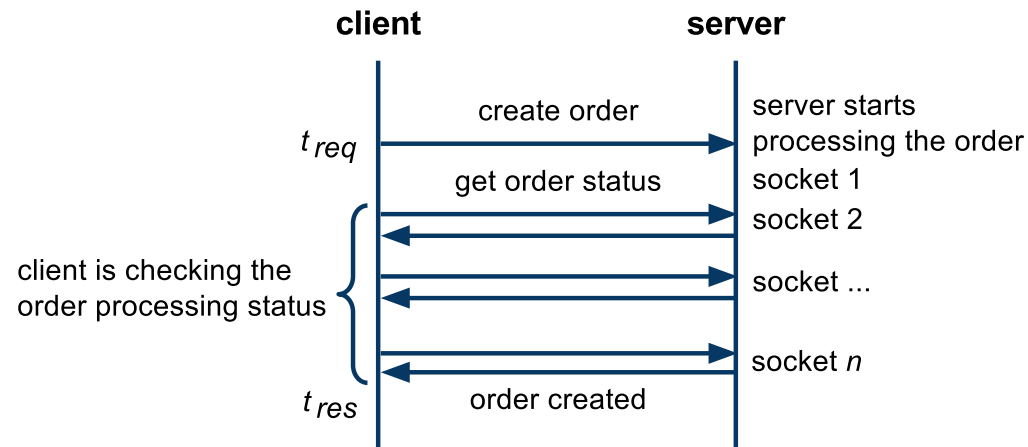

- Synchronous
 - one socket, $|t_{req} - t_{res}|$ is small
 - easy to implement and deploy, only standard firewall config
 - only the server defines endpoint
- Asynchronous
 - request, response each has socket, client and server define endpoints
 - $|t_{req} - t_{res}|$ can be large (hours, even days)
 - harder to do across network elements (private/public networks issue)

Asynchronous via Intermediary

- Intermediary
 - *A component that decouples a client-server communication*
 - *It increases reliability and performance*
 - *The server may not be available when a client sends a request*
 - *There can be multiple servers that can handle the request*
- Further Concepts
 - *Message Queues (MQ) – queue-based communication*
 - *Publish/Subscribe (P/S) – event-driven communication*

Asynchronous via Polling

- Polling – only clients open sockets
 - *A client performs multiple request-response interactions*
 - *The first interaction initiates a process on the server*
 - *Subsequent interactions check for the processing status*
 - *The last interaction retrieves the processing result*
- Properties of environments
 - *A server cannot open a socket with the client (network restrictions)*
 - *Typically on the Web (a client runs in a browser)*

Overview

- Introduction to Application Protocols
 - *Synchronous and Asynchronous Communication*
 - *Selected Networking Concepts*
- Introduction to HTTP

Public/Private Network Configuration

- Adds complexity to configuration of application
 - *Config example at server with `eth0 = 147.32.100.1` (iptables)*

```
1 # enable ip forwarding from one interface to another within linux core
2 echo 1 > /proc/sys/net/ipv4/ip_forward
3
4 # redirect all communication coming to tcp/3000 to 192.168.1.2:4000
5 iptables -t nat -A PREROUTING -i eth0 -p tcp --dport 3000 -j DNAT \
6     --to-dest 192.168.1.2 --to-port 4000
```

Virtual Private Network

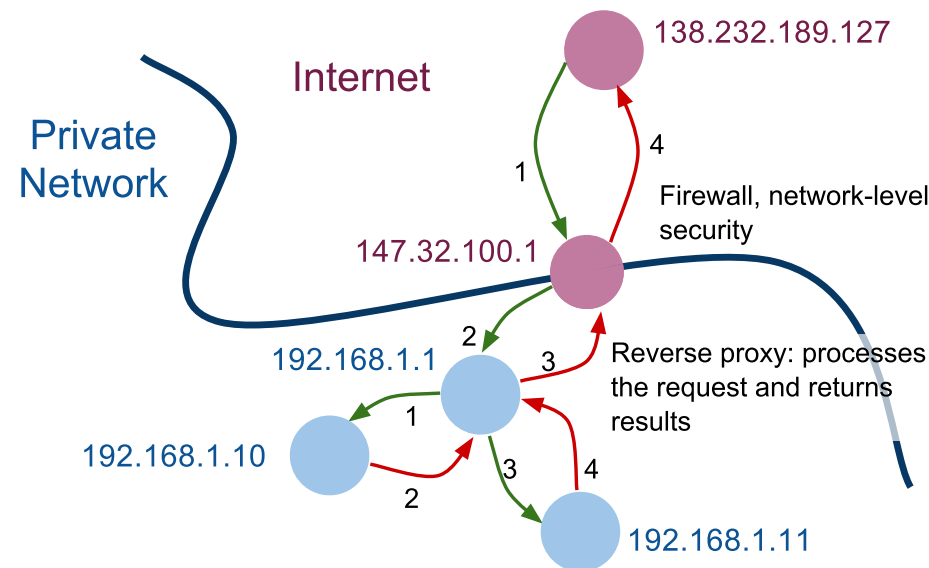

- VPN = Virtual Private Network
 - *an overlay network between a client and a server*
 - *the network spans accross underlying network elements*
 - *Example:*
 - *VPN client starts a VPN connection with the VPN server via network interfaces*
 - *VPN server assigns an IP address to the VPN client from the server's subnet*
 - *Packets in VPN communication are encrypted and sent out in an outer VPN packet, e.g. IPSec packet*

Forward Proxy

- Forward Proxy
 - Centralized access control based on content
 - The client knows about the site it wants to access
 - Performs request on behalf of the client
 - Caches content to increase performance, limits network traffic
 - Filters requests or controls access based on destinations or origins
 - Widely used in private networks in companies
 - Most of the proxy servers today are Web proxy servers

Reverse Proxy

- Reverse Proxy
 - *Aggregates multiple request-response interactions with back-end systems*
 - *Processes the request on behalf of the client*
 - *The client does not know about the back-end systems*
 - *May provide additional capabilities*
 - *Data transformations*
 - *Security – authentication, authorization*
 - *Orchestration of communication with back-end systems*

Overview

- Introduction to Application Protocols
- Introduction to HTTP
 - *State Management*

Hypertext Transfer Protocol – HTTP

- Application protocol, basis of Web architecture
 - *Part of HTTP, URI, and HTML family*
 - *Request-response protocol*
- One socket for single request-response
 - *original specification*
 - *have changed due to performance issues*
 - *many concurrent requests*
 - *overhead when establishing same connections*
 - *HTTP 1.1 offers persistent connection and pipelining*
- HTTP is stateless
 - *Multiple HTTP requests cannot be normally related at the server*
 - *"problems" with state management*
 - *REST goes back to the original HTTP idea*

HTTP Request and Response

- Request Syntax

```
method uri http-version <crLf>
(header : value <crLf>)*
<crLf>
[ data ]
```

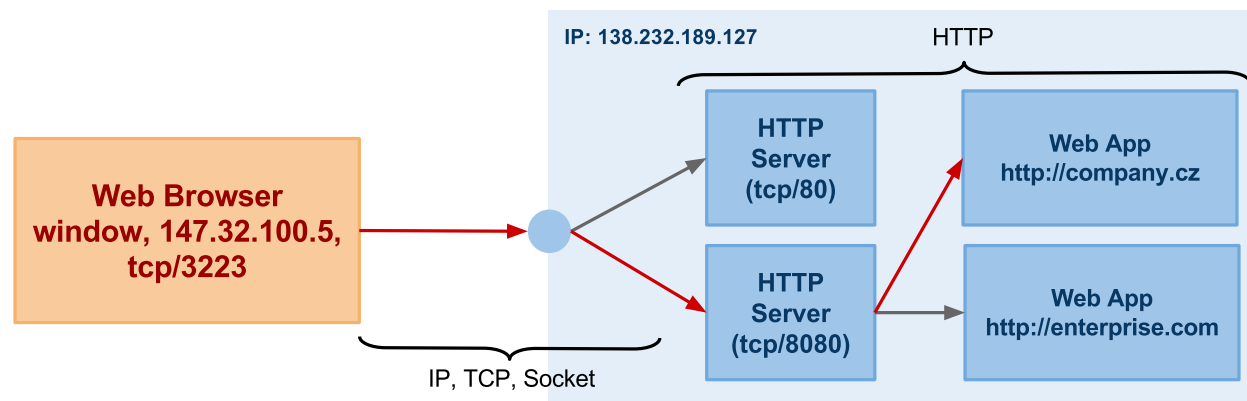

- Response Syntax

```
http-version response-code [ message ] <crLf>
(header : value <crLf>)*
<crLf>
[ data ]
```

- Semantics of terms

method	= "GET" "POST" "DELETE" "PUT" "HEAD" "OPTIONS"
uri	= [path] [";" params] ["?" query]
http-version	= "HTTP/1.0" "HTTP/1.1"
response-code	= valid response code
header : value	= valid HTTP header and its value
data	= resource state representation (hypertext)

Serving HTTP Request

- IP and TCP addressing
 1. User enters URL `http://company.cz:8080/orders` to the browser
 2. Browser gets an IP address for `company.cz`, `IP:138.232.189.127`
 3. Browser and Web Server creates a socket
`[147.32.100.5:3223;138.232.189.127:8080]`
- Application addressing
 4. Browser sends HTTP request, that is, writes following data to the socket
 - 1 | GET /orders HTTP/1.1
 - 2 | Host: company.cz
 5. Web server passes the request to the web application `company.cz` which serves `GET orders` and that writes a response back to the socket.

HTTP Listener

- HTTP listener implementation in Java using Jetty 
 - Server listens on port **8080**
 - Jetty parses HTTP request data into **HttpServletRequest** object.
 - When a client connects, the method **handleRequest** is called
 - The method tests the value of the **host** header and responds back if the header matches **company.cz** value.

```
1  /** handles the request when client connects */
2  public void handleRequest(HttpServletRequest request,
3                          HttpServletResponse response) throws IOException, ServletException {
4
5      // test if the host is company.cz
6      if (request.getHeader("Host").equals("company.cz")) {
7          response.setStatus(200);
8          response.setHeader("Content-Type", "text/plain");
9          response.getWriter().write("This is the response");
10         response.flushBuffer();
11     } else
12         response.sendError(400); // bad request
13 }
```

HTTP Listener (Cont.)

- Test it using Telnet

```
1 telnet 127.0.0.1 8080
2 # ...lines omitted due to brevity
3 GET /orders HTTP/1.1
4 Host: company.cz
5
6 HTTP/1.1 201 OK
7 Content-Type: plain/text
8
9 This is the response...
```

- HTTP listener in bash

- *Use it to test incoming HTTP connections quickly*
- *Uses **nc** utility (netcat)*

```
1 # ctrl-c to stop http listener
2 control_c() {
3     echo -en "\n* Exiting\n"
4     exit $?
5 }
6 trap control_c SIGINT
7
8 for (( ; ; ))
9 do
10     echo -e "\n\n* Listening on port $1..."
11     echo -e "\nHTTP/1.0 204 No Content\n\n" | nc -l $port
12 done
```

Virtual Web Server

- Virtual server
 - *Configuration of a named virtual web server*
 - *Web server uses host request header to distinguish among multiple virtual web servers on a single physical host.*
- Apache virtual Web server configuration
 - *Two virtual servers hosted on a single physical host*

```
1  # all IP addresses will be used for named virtual hosts
2  NameVirtualHost *:80
3
4  <VirtualHost *:80>
5      ServerName company.com
6      ServerAdmin admin@company.com
7      DocumentRoot /var/www/apache/company.com
8  </VirtualHost>
9
10 <VirtualHost *:80>
11     ServerName firm.cz
12     ServerAdmin admin@firm.cz
13     DocumentRoot /var/www/apache/firm.cz
14 </VirtualHost>
```

Better Support for HTTP Testing

- Use **curl** to test HTTP protocol

```
1 Usage: curl [options...] <url>
2
3 -X/--request <command>      Specify request command to use
4 -H/--header <line>          Custom header to pass to server
5 -d/--data <data>            HTTP POST data
6 -b/--cookie <name=string/file> Cookie string or file to read cookies from
7 -v/--verbose                Make the operation more talkative
```

- Example

```
1 curl -v -H "Host: company.cz" 127.0.0.1:8080
2
3 * About to connect() to 127.0.0.1 port 8080
4 * Trying 127.0.0.1... connected
5 * Connected to 127.0.0.1 port 8080
6 > GET / HTTP/1.1
7 > User-Agent: curl/7.20.0 (i386-apple-darwin10.3.2) libcurl/7.20.0 OpenSSL/0.9.8n
8 > Accept: */*
9 > Host: company.cz
10 >
11 < HTTP/1.1 201 OK
12 < Connection: keep-alive
13 < Content-Type: plain/text
14 <
15 < This is the response...
```

Overview

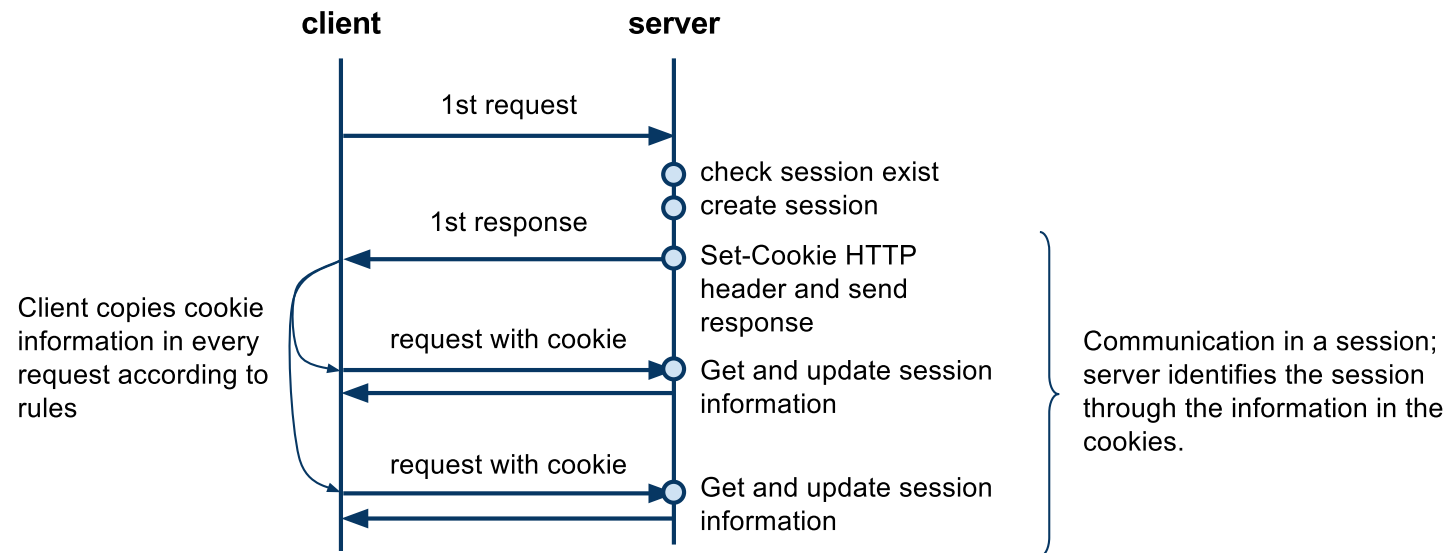

- Introduction to Application Protocols
- Introduction to HTTP
 - *State Management*

State Management

- HTTP is a stateless protocol – original design
 - *No information to relate multiple interactions at server-side*
 - Except **Authorization** header is copied in every request
 - IP addresses do not work, one public IP can be shared by multiple clients
- Solutions to check for a valid state at server-side
 - **Cookies** – obvious and the most common workaround
 - RFC 2109 – HTTP State Management Mechanism [↗](#)
 - Allow clients and servers to talk in a context called **sessions**
 - **Hypertext** – original HTTP design principle
 - App states represented by resources (hypermedia), links define transitions between states
 - Adopted by the REST principle **statelessness**

Interaction with Cookies

- Request-response interaction with cookies
 - *Session is a logical channel maintained by the server*

- Stateful Server
 - *Server remembers the session information in a server memory*
 - *Server memory is a non-persistent storage, when server restarts the memory content is lost!*

Set-Cookie and Cookie Headers

- **Set-Cookie** response header

```
1 set-cookie = "Set-Cookie:" cookie ("," cookie)*  
2   cookie    = NAME "=" VALUE (";" cookie-av)*  
3   cookie-av = "Comment" "=" value  
4             | "Domain" "=" value  
5             | "Max-Age" "=" value  
6             | "Path" "=" value
```

- **domain** – *a domain for which the cookie is applied*
- **Max-Age** – *number of seconds the cookie is valid*
- **Path** – *URL path for which the cookie is applied*

- **Cookie** request header. A client sends the cookie in a request if:

- **domain** *matches the origin server's fully-qualified host name*
- **path** *matches a prefix of the request-URI*
- **Max-Age** *has not expired*

```
1 cookie = "Cookie:" cookie-value (";" cookie-value)*  
2   cookie-value = NAME "=" VALUE [";" path] [";" domain]  
3   path        = "$Path" "=" value  
4   domain      = "$Domain" "=" value
```

- **domain**, and **path** *are values from corresponding attributes of the Set-Cookie header*

Session Management Java Class

- Manages client sessions in a server memory 

```
1  public class Sessions<E> {
2
3      // storage for the session data;
4      private Hashtable<String, E> sessions = new Hashtable<String, E>();
5
6      /** Returns session id based on the information in the http request */
7      public String getSessionID(HttpServletRequest request) throws Exception {
8          String sid = null;
9
10         // extract the session id from the cookie
11         if (request.getHeader("cookie") != null) {
12             Pattern p = Pattern.compile(".*session-id=([a-zA-Z0-9]+).*");
13             Matcher m = p.matcher(request.getHeader("cookie"));
14             if (m.matches()) sid = m.group(1);
15         }
16
17         // create the session id md5 hash; use random number to generate a client-id
18         // note that this is a simple solution but not very reliable
19         if (sid == null || sessions.get(sid) == null) {
20             MessageDigest md = MessageDigest.getInstance("MD5");
21             md.update(new String(request.getRemoteAddr() +
22                                 Math.floor(Math.random()*1000)).getBytes());
23             sid = Utils.toHexString(md.digest());
24         }
25         return sid;
26     }
27
28     public E getData(String sid) ... // returns session data from sessions object
29     public void setData(String sid, E d) ... // sets session data to sessions object
30 }
```

Stateful Server Implementation

- Simple per-client counter 

```
1 public void handleRequest(HttpServletRequest request,
2     HttpServletResponse response) throws Exception {
3     // get the session id
4     String sid = sessions.getSessionID(request);
5
6     // create the new data if none exists
7     if (sessions.getData(sid) != null)
8         sessions.setData(sid,
9             Integer.valueOf(sessions.getData(sid).intValue() + 1));
10    else
11        sessions.setData(sid, Integer.valueOf(1));
12
13    // send the response
14    response.setStatus(200);
15    response.setHeader("Set-Cookie", "session-id="+ sid + "; MaxAge=3600");
16    response.setHeader("Content-Type", "text/plain");
17    response.getWriter().write("Number of hits from you: " +
18        sessions.getData(sid).toString());
19    response.flushBuffer();
20 }
```

Task

- *What happens when the server restarts?*
- *How do you change the code to count requests from all clients?*

Testing

- Testing

- `curl` will require you to specify cookies in every request
- Browser handles cookies automatically

```
1  # run curl for the first time
2  curl -v 127.0.0.1:8080
3  > GET / HTTP/1.1
4  > Host: 127.0.0.1:8080
5  >
6  < HTTP/1.1 200 OK
7  < Set-Cookie: session-id=3a9c3cdc5ff36434aa1ba860727ca401;max-age=3600
8  <
9  Number of hits from you: 1
10
11 # copy the cookie session-id from previous response
12 curl -v -b session-id=3a9c3cdc5ff36434aa1ba860727ca401 127.0.0.1:8080
13 > GET / HTTP/1.1
14 > Host: 127.0.0.1:9900
15 > Cookie: session-id=3a9c3cdc5ff36434aa1ba860727ca401
16 >
17 < HTTP/1.1 200 OK
18 < Set-Cookie: session-id=3a9c3cdc5ff36434aa1ba860727ca401;max-age=3600
19 <
20 Number of hits from you: 2
```
