Humla v0.3

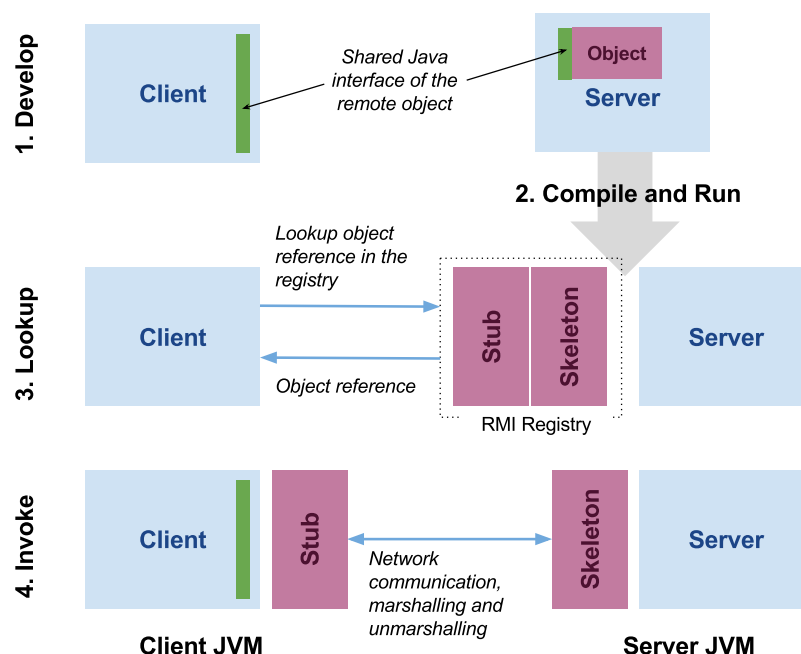

Overview

- Java Technologies and Services
 - *Remote Method Invocation*
 - *Java Database Connectivity*
 - *Java Naming and Directory Interface*
 - *Application Server and JNDI*
 - *Two-phase Commit*

Overview

- Communication among Java-based applications
 - *Methods of a Java class can be invoked by other Java class remotely*
 - *Uses Java Remote Method Protocol (JRMP)*
 - *Java-specific application protocol over TCP/IP*
 - *Basis for JEE technologies, such as JMS*
- Terminology
 - **Client** – *a program that invokes a remote method*
 - **Server** – *a program that exports a remote object*
 - **Stub** – *a representation of the client-side object for communication*
 - **Skeleton** – *a representation of the server-side object for communication*
 - **Registry** – *a component that holds a stub*
 - **Marshalling/Unmarshalling** – *a process of transforming memory representation of the object to a form suitable for network transmission and vice-versa*

Architecture

RMI Implementation in Java – Interface

- Shared interface

```
1  import java.rmi.Remote;
2  import java.rmi.RemoteException;
3
4  // shared interface between a client and a server to
5  // invoke methods on the remote object
6  public interface HelloRMIIInterface extends Remote {
7      public String calculate(int a, int b) throws RemoteException;
8  }
```

- RMI Server

```
1  import java.rmi.Naming;
2  import java.rmi.RemoteException;
3  import java.rmi.RMISecurityManager;
4  import java.rmi.server.UnicastRemoteObject;
5  import java.rmi.registry.LocateRegistry;
6
7  public class Server extends UnicastRemoteObject implements HelloRMIIInterface {
8
9      // implementation of the interface method
10     public int calculate(int a, int b) throws RemoteException {
11         return a+b;
12     }
```

RMI Implementation in Java – Server

- RMI Server (cont.)

```
1  // start the server and register the object in the rmi registry
2  public static void main(String args[]) {
3      try {
4          // install a security manager (uses a security policy)
5          if (System.getSecurityManager() == null) {
6              RMISecurityManager sm = new RMISecurityManager();
7              System.setSecurityManager(sm);
8          }
9
10         // create rmi registry
11         LocateRegistry.createRegistry(1099);
12
13         // create remote object
14         Server obj = new Server();
15
16         // Bind the object instance to the name "HelloRMI"
17         // 0.0.0.0 denotes the service will listen on all network interfaces
18         Naming.rebind("//0.0.0.0/HelloRMI", obj);
19
20         System.out.println("RMI server started, " +
21             "listening to incoming requests...");
22     } catch (Exception e) {
23         System.out.println("Error occurred: " + e.getLocalizedMessage());
24     }
25 }
26
```

RMI Implementation in Java – Client

- RMI Client

```
1  import java.rmi.Naming;
2
3  public class Client {
4
5      public static void main(String args[]) throws Exception {
6          // get a reference to the remote object
7          // assuming the server is running on the localhost
8          HelloRMIInterface o = (HelloRMIInterface)
9              Naming.lookup("//localhost/HelloRMI");
10
11         // call the object method
12         System.out.println(o.calculate(6, 4));
13     }
14 }
```

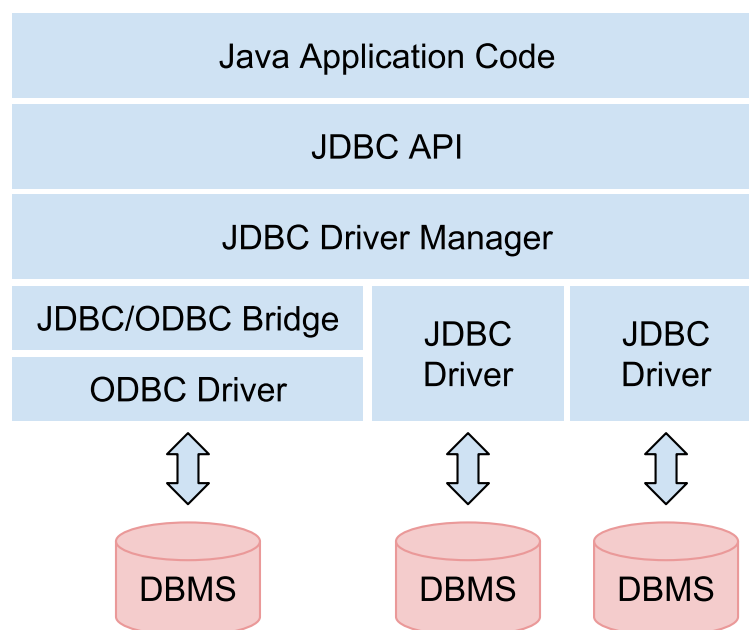

Overview

- Java Technologies and Services
 - Remote Method Invocation
 - *Java Database Connectivity*
 - Java Naming and Directory Interface
 - Application Server and JNDI
 - Two-phase Commit

Overview

- Uniform API to access any kind of tabular data
 - No need to deal with specific APIs of DBMS vendors
- JDBC components
 - JDBC API
 - defines methods to execute SQL statements and retrieve results
 - Driver Manager
 - provides drivers that provide access to a specific DBMS
 - they implement a specific protocol to access the DBMS
 - JDBC-ODBC Bridge
 - a software bridge which provides access via ODBC drivers
 - ODBC driver is a driver in C for accessing DBMS

JDBC Architecture

JDBC Example Implementation in Java

- JDBC Client

```
1  import java.sql.*;
2
3  public class JDBCClient {
4
5      public static void main(String args[]){
6          // database url
7          String db_url = "jdbc:oracle:thin:@czns20sr:33001:XE";
8
9          // username and password
10         String username = "myUsername";
11         String password = "myPassword";
12
13         try {
14             // Register JDBC driver
15             Class.forName("oracle.jdbc.driver.OracleDriver");
16
17             // Open a connection
18             Connection con = DriverManager.getConnection(
19                 db_url, username, password);
20
21             // Create and execute query statement
22             Statement stmt = con.createStatement();
23             String sql = "SELECT id, first, last, age FROM Employees";
24             ResultSet rs = stmt.executeQuery(sql);
25
```

JDBC Example Implementation in Java

- JDBC Client (cont.)

```
25         // Loop and extract received data
26         while (rs.next()) {
27             int id = rs.getInt("id");
28             int age = rs.getInt("age");
29             String first = rs.getString("first");
30             String last = rs.getString("last");
31         }
32
33         // Release the connections
34         rs.close();
35         stmt.close();
36         conn.close();
37     }catch(SQLException se){
38
39         //Handle errors for JDBC
40         se.printStackTrace();
41     }catch(Exception e){
42
43         //Handle errors for Class.forName
44         e.printStackTrace();
45     }
46 }
47
48
```

Overview

- Java Technologies and Services
 - *Remote Method Invocation*
 - *Java Database Connectivity*
 - *Java Naming and Directory Interface*
 - *Application Server and JNDI*
 - *Two-phase Commit*

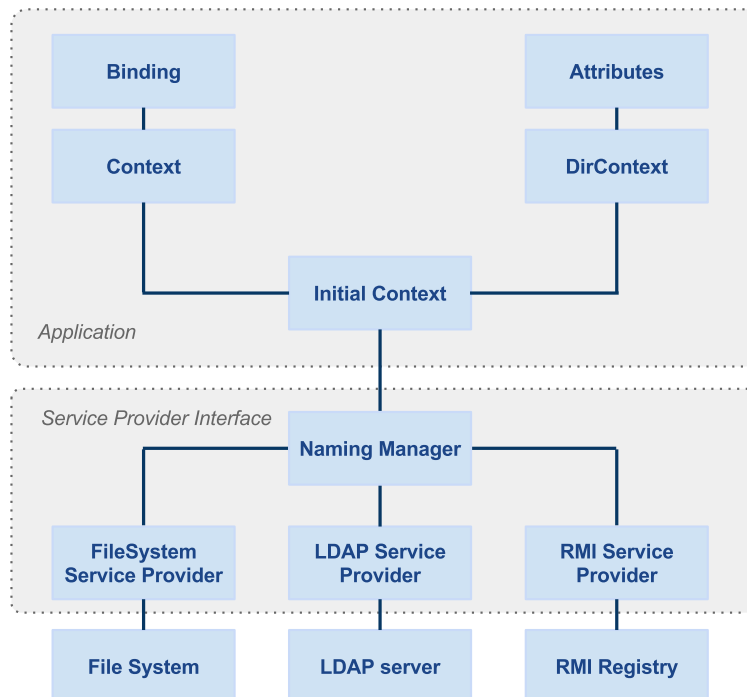

Overview

- Objectives
 - *Allows to access objects by names in various directory systems and their attributes*
 - *Independent of any specific directory service implementation*
 - *Enables to distribute Java objects across various systems in the environment*
- Terminology
 - *Binding – association between a name and a object*
 - *Context – a set of bindings*
- JNDI Provides:
 - *a mechanism to bind an object to a name.*
 - *a directory lookup interface*
 - *a pluggable service provider interface (SPI) – any directory service implementation can be plugged in*

JNDI Packages

- Naming Package
 - *interfaces to access naming services*
 - *Context: looking up, binding/unbinding, renaming, objects*
- Directory Package
 - *allows to retrieve attributes of objects, and to search for objects*
- Event Package
 - *allows for event notification in naming and directory services*
 - *For example, object was added, object changed, etc.*
- Other packages
 - *LDAP – allows to access LDAP services*
 - *Service Provider Interface – allows to develop various naming/directory services*

JNDI Architecture

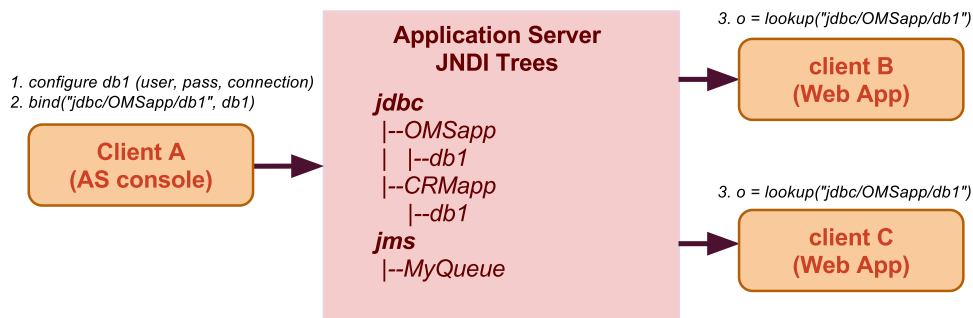

Application Server and JNDI

- Distribution of objects
 - *Application Server provides central directory for various kinds of objects*
 - *Datasources, JMS queues and topics, etc.*
 - *Clients store objects in the central directory*
 - *Administrator configures objects using Application Server Console or via AS API*
 - *Clients retrieve objects from the central directory*
- Benefits
 - *replication of objects across clients*
 - *central configuration of objects' parameters*
 - *scalability – allowing/disabling connections as required*

Overview

- Java Technologies and Services
 - *Remote Method Invocation*
 - *Java Database Connectivity*
 - *Java Naming and Directory Interface*
 - *Application Server and JNDI*
 - *Two-phase Commit*

Application Server and JNDI

- **Example Scenario**

- *Client A creates a datasource, configures it and registers it in the JNDI tree*
 - *Client A is a Admin server console app; this task is performed by the administrator*
- *Client B and C lookup the object under specific JNDI name and retrieves the object from the tree*
 - *They get the object from the tree and use it to connect to the DB*
 - *They do not need to know any DB specific details, the object is pre-configured from the server*

Example Datasource in Weblogic

The screenshot shows the 'Settings for order-db' configuration page in Weblogic. The 'Configuration' tab is selected, and the 'General' sub-tab is active. The page contains the following fields and options:

- Name:** order-db
- JNDI Name:** jdbc/order-db
- ☐ **Row Prefetch Enabled**
- Row Prefetch Size:** 48
- Stream Chunk Size:** 256

There are 'Save' buttons at the top and bottom of the configuration area. A note at the top states: 'Click the **Lock & Edit** button in the Change Center to modify the settings on this page.'

Targets

- Object
 - A service provided by the application server, e.g. datasources, JMS queue, SAF
- Types of services
 - Pinned services
 - Objects targeted to a single server only
 - Cluster services
 - Objects targeted to all servers in the cluster

Example Target Configuration

Settings for order-db

Configuration **Targets** Monitoring Control Security Notes

Click the **Lock & Edit** button in the Change Center to modify the settings on this page.

Save

This page allows you to select the servers or clusters on which you would like to deploy this JDBC data source.

Servers

☐ SOA_AdminServer

Clusters

☒ SOA_Cluster

- ☒ All servers in the cluster
- ☐ Part of the cluster
 - ☐ WLS_SOA1
 - ☐ WLS_SOA2
 - ☐ WLS_SOA3

☐ WSM_PM-Cluster

- ☐ All servers in the cluster
- ☐ Part of the cluster
 - ☐ WLS_WSM1

Save

Click the **Lock & Edit** button in the Change Center to modify the settings on this page.

Cluster-wide JNDI Tree

- Cluster
 - Every managed server has its own JNDI tree
 - Servers in a cluster sync up their JNDI trees as per the target configuration
 - A stub of the object appears in every managed server's JNDI tree
- When a client retrieves an object from the tree
 1. Client connects to the cluster using the cluster address
 2. Client creates an initial context (represents a naming service)
 3. Client uses the initial context to lookup objects
 4. The naming service can failover to a next available managed server when lookup fails

Example JNDI Tree on Weblogic Server

The screenshot displays the Oracle WebLogic Server Administration Console. On the left, the 'JNDI Tree Structure' is shown, listing various services under the 'WLS_SOA1' domain, including AGMetadataService, AGQueryService, AuditServiceBean#oracle, BPELActivityManagerBean, BPELAuditTrailBean, BPELInstanceManagerBean, BPELProcessManagerBean, BPELServerManagerBean, BPELTestInstanceManager, BPMAnalytics#oracle, BPMJMSServer_auto_1@jms, BPMJMSServer_auto_2@jms, BPMJMSServer_auto_3@jms, BPMNActivityManagerBean, BPMNInstanceManagerBean, BPMNProcessManagerBean, CompositeMetadataServiceBean, DiagnosticService, eis, ExalogicOptimizedFileAdapter, and FileAdapter. On the right, the 'Settings for jdbc.order-db' page is shown, with the 'Overview' tab selected. It displays the binding name 'jdbc.order-db', the class 'weblogic.jdbc.common.internal.RmiDataSource_1036_WLStub', and the hash code '399376309'. The 'toString' results show a clusterable remote reference with failover capabilities across multiple managed servers.

JNDI Implementation in Java

- Lookup for bound object

```
1  import javax.naming.InitialContext;
2  import java.util.*;
3  import javax.sql.*;
4
5  ...
6
7  Properties p = new Properties();
8
9  // configure the service provider url: "t3://localhost:7001"
10 p.put(Context.PROVIDER_URL,
11       "t3://czfmwapp03-vf:8001,czfmwapp04-vf:8001,czfmwapp05-vf:8001");
12
13 // configure the initial context factory.
14 // we use WebLogic context factory
15 p.put(Context.INITIAL_CONTEXT_FACTORY,
16       "weblogic.jndi.WLInitialContextFactory");
17 InitialContext ctx = new InitialContext(p);
18
19 dataSource =
20     (DataSource) ctx.lookup("jdbc/order-db");
21
22 // invoke the object method
23 Connection c = dataSource.getConnection();
24
```

Overview

- Java Technologies and Services
 - Remote Method Invocation
 - Java Database Connectivity
 - Java Naming and Directory Interface
 - Application Server and JNDI
 - *Two-phase Commit*

Overview

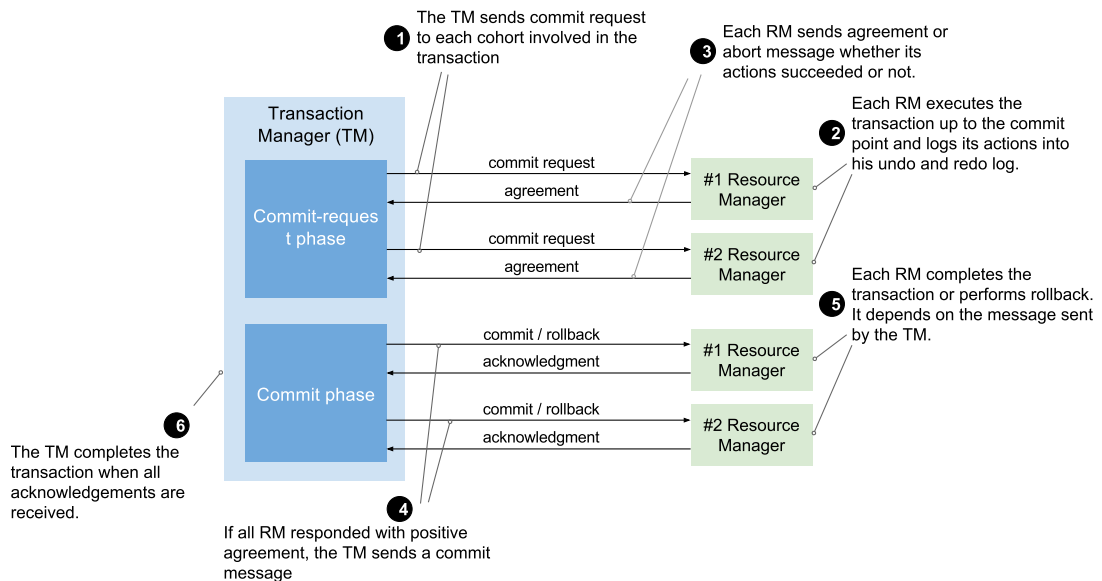

- Coordination of a distributed transaction
 - *All transaction operations are completed across multiple resources; or none is completed*
 - *Able to deal with many types of failures (process, network, communication)*
- Terminology
 - **Transaction Manager** – *manages transactions, coordinates decisions for commit or rollback, and coordinates failure recovery*
 - **Resource Manager** – *manages an access to a resource that participates in the transaction, e.g. DBMS, JMS*
 - **Agreement** – *an agreement message sent by the Resource Manager, whether the operation was processed successfully*
 - **Acknowledgment** – *a message about a status of the operation execution*
 - **Rollback** – *operation that returns the Resource Manager state to its pre-transaction state.*

X/Open – eXtended Architecture (XA)

- Standard for executing distributed transactions
 - *Specifies how the coordinator will roll up the transaction against involved different systems.*
 - *Based on the Two-phase Commit protocol.*
 - *Defines interface between the coordinator and each system node.*
 - *Single transaction access to multiple resources (e.g. message queues, databases, etc.)*
 - *Defined in the eXtended Architecture Specification* [🔗](#)
- Wide technological support
 - *Java Transaction API (JTA) [🔗](#) – distributed transactions in a Java environment.*
 - *Supported in the Oracle Service Bus through a JMS queue.*
 - *MySQL Relational Database Management System (since v5.0)*

Two-phase Commit

- Two-phase commit scenario

XA Example Implementation in Java

- Distributed Transaction

```

1  import java.sql.*;
2  import javax.sql.*;
3  import javax.naming.*;
4  import java.util.*;
5
6  public class Server {
7
8      public static void main(String args[]) {
9
10         // Initialize context
11         Hashtable parms = new Hashtable();
12         parms.put(Context.INITIAL_CONTEXT_FACTORY,
13             "weblogic.jndi.WLInitialContextFactory");
14         parms.put(Context.PROVIDER_URL, "t3://localhost:7001");
15         InitialContext ctx = new InitialContext(parms);
16
17         // Perform a naming service lookup to get UserTransaction object
18         javax.transaction.UserTransaction usertx;
19         usertx = (UserTransaction) ctx.lookup("java:comp/UserTransaction");
20
21         try {
22             //Start a new user transaction.
23             usertx.begin();

```

XA Example Implementation in Java

- Distributed Transaction (cont.)

```
24 // Establish a connection with the first database
25 javax.sql.DataSource data1;
26 data1=(javax.sql.DataSource)ctx.lookup("java:comp/env/jdbc/DataBase1");
27 java.sql.Connection conn1 = data1.getConnection();
28 java.sql.Statement stat1 = conn1.createStatement();
29 // Establish a connection with the second database
30 javax.sql.DataSource data2;
31 data2=(javax.sql.DataSource)ctx.lookup("java:comp/env/jdbc/DataBase2");
32 java.sql.Connection conn2 = data2.getConnection();
33 java.sql.Statement stat2 = conn2.createStatement();
34
35 // Execute update query to both databases
36 stat1.executeUpdate(...);
37 stat2.executeUpdate(...);
38
39 // Commit the transaction
40 // Apply the changes to the participating databases
41 usertx.commit();
42
43 //Release all connections and statements.
44 stat1.close();
45 stat2.close();
46 conn1.close();
47 conn2.close();
```

XA Example Implementation in Java

- Distributed Transaction (cont.)

```
48 // Catch any type of exception
49 catch (java.lang.Exception e) {
50     try {
51         e.printStackTrace();
52
53         // Rollback the transaction
54         usertx.rollback();
55         System.out.println("The transaction is rolled back.");
56     } catch (java.lang.Exception ex) {
57         e.printStackTrace();
58         System.out.println("Exception is caught. Check stack trace.");
59     }
60 }
61 }
```
