### **Overview**

- Application Server Architecture
- Distribution of Objects

## **Application Server Overview**

### • An environment that runs an application logic

- A client communicates with the server using an application protocol

### Application Server

- A modular environment
  - → provides technology to realize enterprise systems
  - → JEE containers Java technology for AS components
  - → Supports a variety of objects such as Servlets, JSPs, JMS
- Provides services such as naming and directory, performance, failover
- Provides Web server capabilities
- Can be a single server or multiple servers

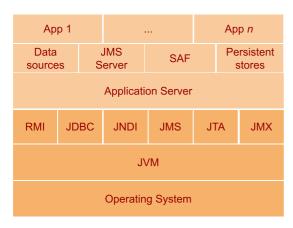

#### • Web Tier – HTTP Server

- Web Server supports HTTP only
- HTTP request/response, security, proxy, caching

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

- 3 -

# **Application Server Layers**

console app, custom-built Web app, middleware apps

shared services used by applications - data sources, JMS queues, JCA adapters

Application Server core libraries, communication management, cluster communication, distributed cache

Java Technology

Java environment, memory management, garbage collection

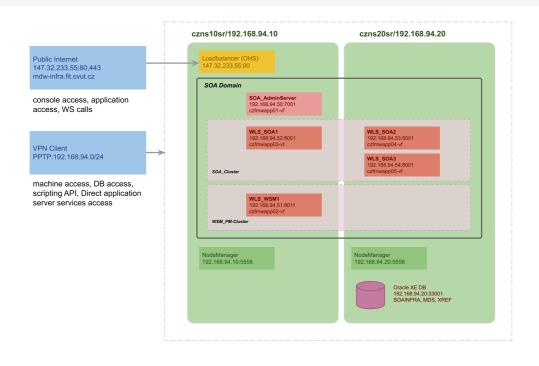

OS services, I/O

#### Features

- AS instance appears as a single process in the OS
  - → you can use standard OS commands to investigate its operation
  - → AS listens on a single or multipe IPs (VIPs) and a tcp port
- AS is a Java process
  - → you can use Java tools to investigate its operation
  - → Garbage collector stats, thread dumps, memory allocations, etc.

- 5 -

# **Terminology**

- Domain
  - A group of servers with specific configuration of applications and objects
- Administration Server
  - An instance of application server that manages the domain
- Managed Server
  - An instance of application server running instances of applications and objects
- Cluster
  - A group of managed servers; they contain the same copy of applications and objects
- Machine
  - A physical machine and OS running one or more servers (Admin or Managed)
- Node Manager
  - A process that provides an access to admin and managed servers on the machine
- Load Balancer
  - A network element that distributes client requests to managed servers based on a specific algorithm

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

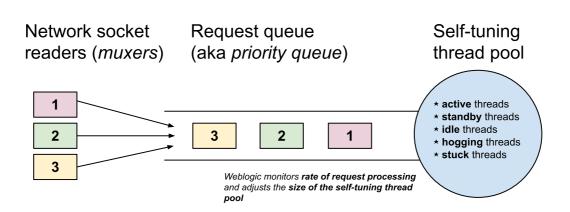

## **Servlet Technology**

- Technology to extend application server functionalities
  - A Java class that can respond to any type of requests
    - $\rightarrow$  A servlet defines an interface for a specific protocol
    - → Your application implements the servlet's interface
- Commonly used to respond to HTTP requests
  - A basis for an application running on an application server
  - HTTP Servlet Java classes
    - $\rightarrow$  HttpServlet provides HTTP protocol interface
    - → HttpServletRequest represents HTTP request
    - → HttpServletResponse represents HTTP response

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

-7-

# Handling Requests in Weblogic

- Muxer component that handles communication via network sockets.
- Request queue queue of requests to be processed.
- **Self-tunning thread pool** a pool of threads in various states.
- Work manager a configuration of maximum threads and a capacity that can be used to handle requests for a specific application/service.

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

### **Overview**

- Application Server Architecture
- Distribution of Objects

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

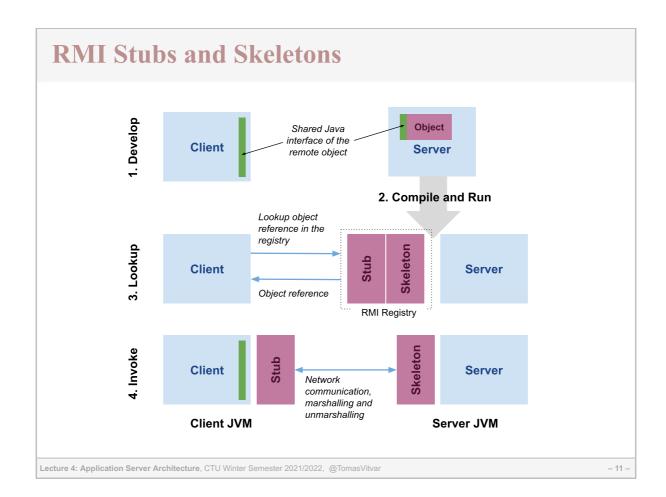

- 9 -

### **Remote Method Invocation**

- Communication among Java-based applications
  - Methods of a Java class can be invoked by other Java class remotely
  - Uses Java Remote Method Protocol (JRMP)
    - → Java-specific application protocol over TCP/IP
  - Basis for JEE technologies, such as JMS
- Terminology
  - Client a program that invokes a remote method
  - Server a program that exports a remote object
  - Stub a representation of the client-side object for communication
  - − *Skeleton* − a representation of the server-side object for communication
  - Registry a component that holds a stub
  - Marshalling/Unmarshalling a process of transforming memory representation of the object to a form suitable for network transmittion and vice-cersa

# **Java Naming and Directory Interface**

### Objectives

- Allows to access objects by names in various directory systems and their attributes
- Independent of any specific directory service implementation
- Enables to distribute Java objects across various systems in the environment

### Terminology

- Binding association between a name and a object
- − Context − a set of bindings

### JNDI Provides:

- a mechanism to bind an object to a name.
- a directory lookup interface
- a pluggable service provider interface (SPI) any directory service implmentation can be plugged in

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

## **Application Server and JNDI**

## • Distribution of objects

- Application Server provides central directory for various kinds of objects
  - → Datasources, JMS queues and topics, etc.
- Clients store objects in the central directory
  - → Administrator configures objects using Application Server Console or via AS API
- Clients retrieve objects from the central directory

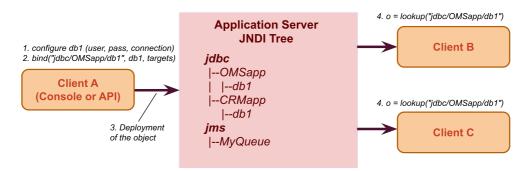

### Benefits

- replication of objects across clients
- central configuration of objects' parameters
- scalability allowing/disabling connections as required

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

- 13 -

## **JNDI Example**

#### • Example Scenario

- Client A creates a datasource, configures it and registeres it in the JNDI tree
   → Client A is a Admin server console app
- Client B and C lookup the object under specific JNDI name and retrieves the object from the tree
  - $\rightarrow$  They get the object from the tree and use it to connect to the DB
  - → They do not need to know any DB specific details
  - $\rightarrow$  The object is pre-configured from the server

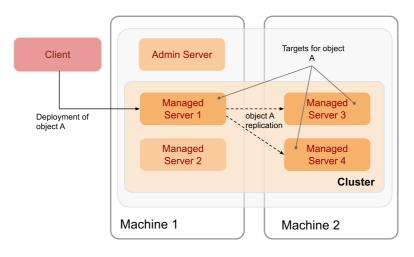

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

– 14 -

### **Deployment to Cluster**

### • Deployment of an object

- Client deploys to one managed server in the cluster
- Object gets replicated to its targets
  - → Targets can be configured for the object, usually all servers but can be selected servers

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

- 15 -

### **Cluster-wide JNDI Tree**

### Cluster

- Every managed server has its own JNDI tree
- Servers in a cluster sync up their JNDI trees as per the target configuration
  - $\rightarrow$  A stub of the object appears in every managed server's JNDI tree
  - → They use JNDI replication service

### When a client retrieves an object from the tree

- 1. Client connects to the cluster using the cluster address
- 2. Client creates an initial context (represents a naming service)
- 3. Client uses the initial context to lookup objects
- 4. Client uses the stub of the object to call the service

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar

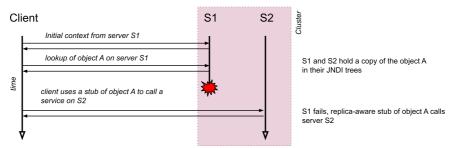

– 16 -

# **Object Failover**

### • Failover

- Failover = ability to locate an object on another server that holds a copy of the object without impact on the performace and configuration

#### Replica-aware stub of object A, failover in cluster

- A client gets a stub of the object by calling lookup on the context
- A client uses the stub of the object to access the object on the server
- When a server fails, **replicate-aware stub** calls the next server that holds the object copy

Lecture 4: Application Server Architecture, CTU Winter Semester 2021/2022, @TomasVitvar
