Faculty of Information Technologies • Software and Web Engineering • https://vitvar.com/lectures

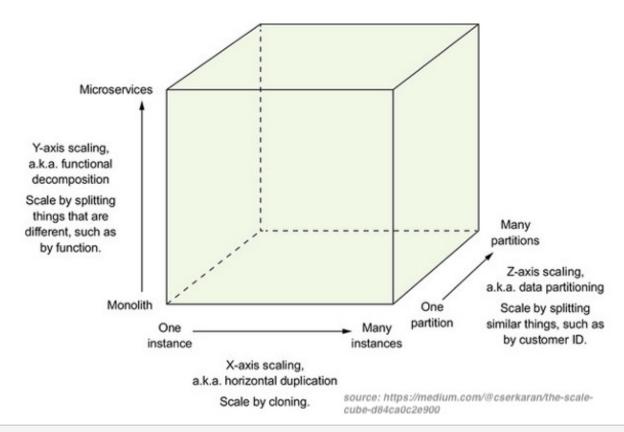

- Microservices Architecture
- Design Patterns

## The Scale Cube

- Three-dimensional scalability model
  - X-Axis scaling requests across multiple instances
  - Y-Axis scaling decomposes an application into micro-services
  - Z-Axis scaling requests across "data partitioned" instances

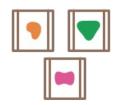

- Emerging software architecture
  - monolithic vs. decoupled applications
  - applications as independenly deployable services

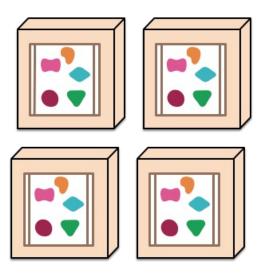

A monolithic application puts all its functionality into a single process...

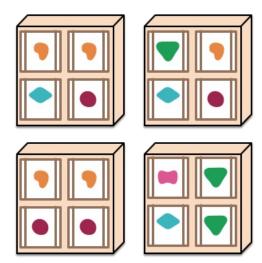

A microservices architecture puts each element of functionality into a separate service...

... and scales by replicating the monolith on multiple servers

... and scales by distributing these services across servers, replicating as needed.

# **Major Characteristics**

- Loosely coupled
  - Integrated using well-defined interfaces
- Technology-agnostic protocols
  - HTTP, they use REST architecture
- Independently deployable and easy to replace
  - A change in small part requires to redeploy only that part
- Organized around capabilities
  - such as accounting, billing, recommendation, etc.
- Impplemented using different technologies
  - polyglot programming languages, databases
- Owned by a small team

- Microservices Architecture
- Design Patterns
  - Data Management Patterns
  - Communication Patterns
  - Other Patterns

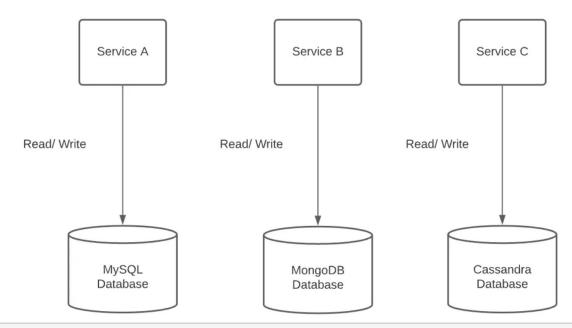

# **Design Patterns**

- Data management patterns
  - Database per service
  - Saga pattern
  - Command query responsibility segregation (CQRS)
- Communication patterns
  - *API Gateway*
  - Aggregator design pattern
  - Circuit breaker design pattern
  - Sidecar pattern
- Other patterns
  - Strangler pattern

- Microservices Architecture
- Design Patterns
  - Data Management Patterns
  - Communication Patterns
  - Other Patterns

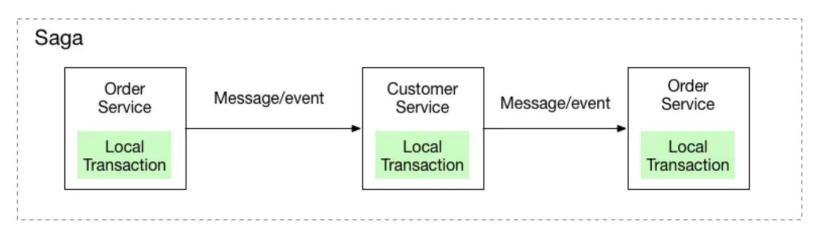

# Database per Service

- Every service has its own database (or at least its own schema)
  - A database dedicated to one service can't be accessed by other services.
  - Decouples services from each other
  - Enables polyglot persistence
    - → Different services can use different database technologies
- Challenges
  - Data consistency
  - Complex queries and transactions

## Saga Pattern

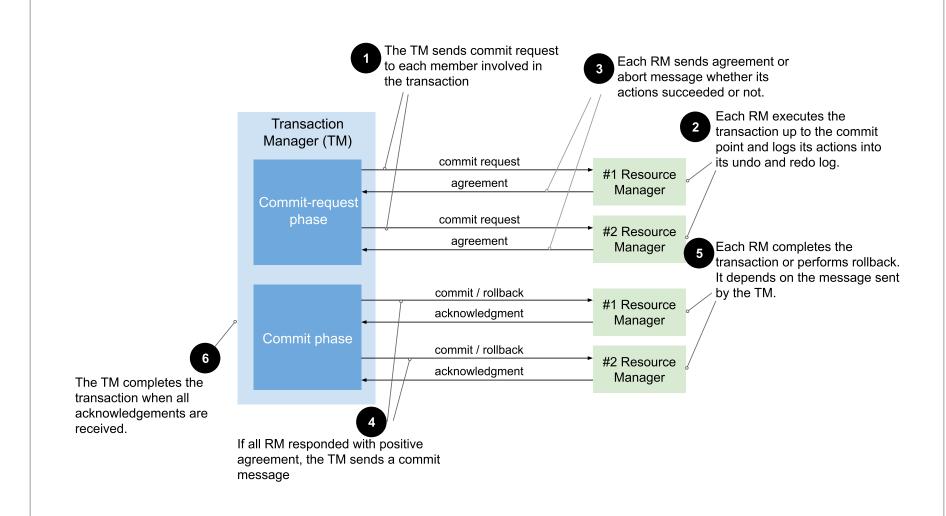

- Manages data consistency across services
  - A series of local transactions
  - This requires compensating transactions to undo changes if needed
  - An alternative to Two-phase commit
- Two types of Sagas
  - Choreography-based Sagas
    - → Each service produces and listens to events
    - $\rightarrow$  No central coordinator
  - Orchestration-based Sagas
    - → Central coordinator (orchestrator) tells the participants what local transactions to execute

# Saga Pattern Examples

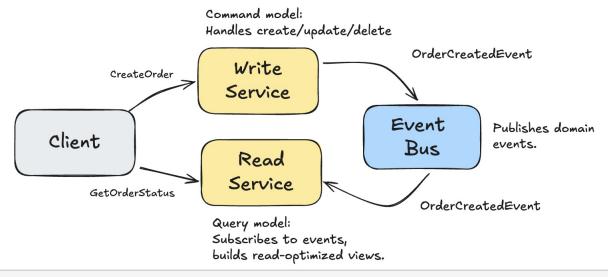

- Example Services
  - Order Service
  - Payment Service
  - Inventory Service
- Choreography (no central coordinator)
  - Order Service  $\rightarrow$  publishes OrderCreated
  - Payment Service → listens, reserves funds → publishes PaymentCompleted
  - Inventory Service  $\rightarrow$  listens, deducts stock  $\rightarrow$  publishes InventoryUpdated
  - Order Service  $\rightarrow$  listens, marks order as Completed
- Orchestration (central coordinator)
  - Orchestrator → sends ReservePayment to Payment Service
  - Payment Service  $\rightarrow$  responds PaymentConfirmed
  - Orchestrator → sends ReserveStock to Inventory Service
  - Inventory Service -> responds StockReserved

# **Two-phase Commit**

# **CQRS**

- Command Query Responsibility Segregation
- A pattern that separates read and write operations in a system.
  - Command side: Handles create/update/delete operations
  - Query side: Handles read operations with optimized views
- Example: Online Order System
  - User places order  $\rightarrow$  CreateOrder
  - Order Service stores order, publishes OrderCreatedEvent
  - Read Service updates denormalized orders\_view
  - Client queries GetOrderStatus → served from orders\_view

- Microservices Architecture
- Design Patterns
  - Data Management Patterns
  - Communication Patterns
  - Other Patterns

# **API Gateway**

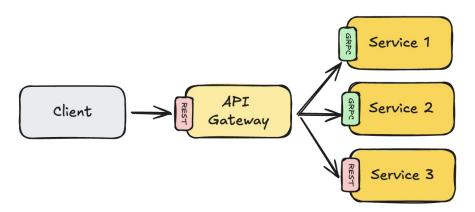

- Single entry point for all clients
  - Handles requests by routing them to the appropriate microservice(s)
  - Perform request aggregation, protocol translation, authentication, rate limiting

#### Benefits

- A single entry point for a group of microservices
- Clients don't need to know how services are partitioned
- Service boundaries can evolve independently
- Can implement authentication, TLS termination and caching

#### Challenges

- Potential bottleneck and single point of failure
- Increased complexity in API Gateway implementation

# **Aggregator Design Pattern**

- Combines data from multiple services into a single response
  - Useful when a client request requires data from multiple microservices
- Benefits
  - Reduces the number of client requests
  - Simplifies client logic
- Challenges
  - Increased complexity in the aggregator service
  - Potential performance bottleneck

## **Circuit Breaker**

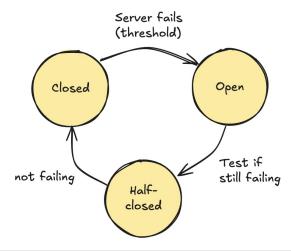

- A service stops trying to execute an operation that is likely to fail
  - Monitors for failures and opens the circuit if failures exceed a threshold
  - When the circuit is open, calls to the failing service are blocked for some time
  - After a timeout, the circuit half-opens to test if the service has recovered
  - If the test call succeeds, the circuit **closes** and normal operation resumes

#### Benefits

- Improves system resilience and stability
- Prevents cascading failures in distributed systems

#### Challenges

- Requires careful configuration of thresholds and timeouts

# Circuit Breaker Example

- Scenario: Order Service calls Payment Service
  - Under normal conditions  $\rightarrow$  call succeeds, response is fast
  - When Payment Service slows down or fails repeatedly → circuit "opens"
  - Further calls are blocked immediately  $\rightarrow$  fallback response returned
  - After a timeout  $\rightarrow$  circuit "half-opens" to test recovery
  - If test succeeds → circuit "closes" and normal calls resume

### • Example Flow

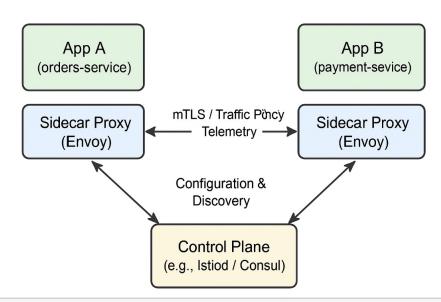

- Order Service  $\rightarrow$  calls Payment API (fails  $3 \times$ )
- Circuit opens → returns "Payment service unavailable"
- After  $30s \rightarrow one trial call allowed$
- If trial succeeds  $\rightarrow$  circuit closes and normal traffic resumes

## **Sidecar Pattern**

- Deploys auxiliary components alongside the main service
  - Handles logging, monitoring, configuration, and networking
  - Runs in a separate process or container but shares the same lifecycle as the main service
- Benefits
  - Decouples auxiliary functionality from the main service
  - Enables reuse of common functionality across multiple services
- Challenges
  - Increased operational complexity
  - Resource overhead due to additional processes/containers

## Sidecar Pattern and Service Mesh

- Service Mesh: A dedicated infrastructure layer for managing service-to-service communication
- Service mesh uses sidecar proxies (e.g. Envoy) to manage traffic
- Example: Istio injects Envoy sidecar to handle
  - Service discovery and routing
  - mTLS security
  - Retries, rate limiting, and metrics

- Microservices Architecture
- Design Patterns
  - Data Management Patterns
  - Communication Patterns
  - Other Patterns

## **Strangler Pattern**

- Incrementally replace a monolith with microservices
- New functionality is implemented as microservices
- Existing functionality is gradually "strangled" and replaced
- Benefits
  - Reduced risk by not rewriting the entire system at once
  - Allows for gradual migration and testing
- Challenges
  - Complexity in managing both monolith and microservices
  - Potential performance overhead during transition
